PROCEEDINGS
of the 28th Annual Conference, International Sustainable Development Research Society

Sustainable Development and Courage:

Culture, Art and Human Rights

Stockholm and online, Sweden

June 14-17, 2022

Sustainable Development and Courage: Culture, Art and Human rights
28th Annual Conference, of the International Sustainable Development Research Society
Stockholm, Sweden, June 15-17, 2022

Proceedings of abstracts, posters and papers that have been accepted after a double blind review process in several stages.

ISBN: 978-91-89504-17-2

Publisher: Södertörn University

Publication year: 2022

Editors: Peter Dobers, Malin Gawell, Johan Gärde, Stefan Silfverskiöld

Welcome message by the Conference Chairs

This summer was a memorable and unique experience for all participants and organisers of the 28th annual conference of the International Sustainable Development Research Society – ISDRS 2022 in Stockholm. On the same turf of the United Nations conference in Stockholm in 1972 and its Stockholm +50 sibbling, and after two annual online versions of the conference forced upon us, it was with great joy and pleasure we met up again in Stockholm, Sweden. With 35+ re-occurring tracks, a hybrid set-up of both on campus and online conferencing, and with six collaborating universities in Stockholm: Marie Cederschiöld University, Stockholm School of Economics, Swedish Defence University, Stockholm University of the Arts, Södertörn University and University College Stockholm, the conference committee truly took us on a complex challenge. . The participants successfully navigated between five different campi while enjoying the this years conference with the overall theme "**Sustainable Development and Courage. Culture, Art and Human Rights**".

We were proud to accommodate over 400 delegates from 50+ countries and all six continents around the world, all of which engaging in the important endeavour of creating more knowledge to make our world a more sustainable one. The six key note panels can be view in its full length on the ISDRS YouTube channel launched in August 2022 with playlists for a few of the recent conferences.[1] For this particular conference panels, please view the playlist for ISDRS 2022.[2]

We want to thank the vice chancellors, communication departments, technical support staff and administrators at the six universities. We furthermore want to thank the ISDRS board, the secretariat, and the NPG: the New Professionals Group. We are thankful to the sponsorship by Ersta Diakoni, allowing twelve scholars from Africa, Asia, Eastern Europe, Middle East and South America to participate online, free of charge.

Last, but not least, a very special THANK YOU to our conference coordinator Johanna Holmberg and her team of about 20 student ambassadors. Without your support this would not have been possible!

- Peter Dobers, Södertörn University
- Malin Gawell, Södertörn University
- Johan Gärde, Marie Cederschiöld University
- Michael Hjälm, University College Stockholm
- Juliette Mapp, Stockholm University of the Arts
- Pierre Guillet de Monthoux, Stockholm School of Economics
- Stefan Silfverskiöld, Swedish Defence University

For any post-conference contacts with the Organising Chairs, please mail us at: isdrs2022@isdrsconferences.org.

Welcome message by the Editors

This document constitutes the published Proceedings of the conference. The volume contains abstracts, full papers and posters accepted after a rigid review process. They were selected for publication in the proceedings after a double-blind review process consisting of two stages, starting with a review and acceptance of an abstract for either oral or poster presentation, and further the opportunity to submit a full paper which was again peer reviewed with a record-large double blind review process.

Authors of abstracts, posters and full papers are searchable in the PDF reader of your choice, such as any keywords of your choice. This kind of publication will most likely remain as an electronic version, never printed out fully in a paper copy of 1700+ pages, and therefore, the most powerful tool of finding texts from ISDRS 2022 in Stockholm, Sweden, is by using the search tool on your computer or electronic device.

Without the help of many hands this achievement would not have been possible. First of all, we would like to express our thankfulness to all the engaged reviewers which invested their time to secure the highest scientific excellence and soundness. The review process was made possible through the support by the many unnamed reviewers.

The main contribution of the proceedings is of course originating from the numerous authors. We express our gratitude to you. Without your dedication and effort the work on this volume would not even have been started. We sincerely hope that the knowledge collected here will continue to make a difference and inspire towards enhanced efforts for transforming our societies in a more sustainable direction.

- Peter Dobers, Södertörn University
- Malin Gawell, Södertörn University
- Johan Gärde, Marie Cederschiöld University
- Stefan Silfverskiöld, Swedish Defence University

For any post-conference contacts with the Editors about this publication, please mail us at: isdrs2022@isdrsconferences.org.

Proud Sponsors of ISDRS 2022

ISDRS 2022 is proud to announce that Ersta Diakoni and Stockholms Sjukhem are very valuable sponsors of the conference allowing us to support twelve scholars, mostly PhD students, from the following nine countries on four different continents to take part in the conference, some of which took part on campus:

- Algeria
- Bangladesh (2 scholars)
- Israel
- Myanmar
- Nigeria (3 scholars)
- Peru
- Russia
- Rwanda
- Ukraine

Ersta Diakoni is gold-level sponsor to ISDRS 2022. Ersta Diakoni has developed and worked with health care and social care since 1851. The organization rests on a Christian foundation. “We see the whole person and want to create a dignified welfare for everyone. As an idea-driven actor, our profit is reinvested in the venture - always with the aim of being able to help more people”. Ersta Diakoni is Sweden's largest player in idea-based health care and social care. They provide health care, social work, education and research and want to continue to grow to be able to offer even more people a dignified welfare. https://www.erstadiakoni.se/

Stockholms Sjukhem is a bronze-level sponsor to ISDRS 2022. Stockholm Sjukhem has cared for people with chronic or long-term illnesses since their inauguration in 1867. Stockholms Sjukhem is a non-profit organization, a private hospital and nursing home owned and operated by a foundation formed in the 1860s. The work is primarily conducted on the basis of care agreements with municipalities and Stockholms county council. Their areas of expertise and profiling are advanced home care, geriatric care, rehabilitation, palliative care and residential care for people with illness because of old age or neurological or dementia illnesses. https://www.stockholmssjukhem.se/

ERSTA DIAKONI

Stockholms Sjukhem

Plenary speakers of the 2022 Conference

Carlton Waterhouse

Carlton Waterhouse serves as the Deputy Assistant Administrator for EPA's Office of Land and Emergency Management. He was appointed by President Biden in February 2021. Carlton began his legal career as an attorney with EPA, where he served in the Office of Regional Counsel in Atlanta, Georgia, and the Office of General Counsel in Washington, D.C. Before rejoining EPA in 2021, he held a joint appointment as a professor at the Howard University School of Law and the Howard University School of Divinity. Carlton is a Fulbright research scholar and an international expert on environmental law and environmental justice.

Azza Karam

Dr. Azza Karam serves as the Secretary General of Religions for Peace – the largest multi-religious leadership platform with over 90 Interreligious Councils, as well as grassroots Interfaith Youth and Women's networks. She also holds a Professorship of Religion and Development at the Vrije Universiteit in Amsterdam (The Netherlands) - of which she is a citizen. She has served in intergovernmental, international and non-governmental organisations since the early 1990s and has lectured in various academic institutions in Europe, North America (including the United States Military Academy/West Point), and in the Arab region. She has published widely on transnational political dynamics, including development, gender and religion.

Prajal Pradhan

Prajal Pradhan studied agricultural engineering and environmental management. He was a lead author of the IPCC Special Report on Climate Change and Land and a contributing author of the AR6 IPCC WG III Report and the AR6 IPCC WG II Report. Prajal has experience in developing relevant research on climate change and sustainable food systems. He is an expert in food system emissions, food security, climate change, and sustainable development goals (SDGs). Currently, Prajal is a PI of the BIO-CLIMAPATHS project. His current research focuses on understanding urban transformations, investigating impacts of climate change on bioeconomy, and SDG interation. Three key words: SDG interactions, Sustainable transformations, Adequate actions.

Björn-Ola Linér

Björn-Ola Linnér is professor in Environmental Change and at the Centre for Climate Science and Policy Research, Linköping University and the programme director of Mistra Geopolitics. His research focuses on transnational governance on climate change and sustainable development goals, societal transformations, the geopolitics of sustainability, and methods for policy analysis and dialogue. His latest books are the co-authored The Political Economy of Climate Change Adaptation (Palgrave MacMillan 2016) and Sustainability Transformations: Agents and Drivers of Social Change (Cambridge University Press 2019).

Sabina Alkire

Sabina Alkire is the Director of the Oxford Poverty and Human Development Initiative (OPHI) and Professor in the Oxford Department of International Development, University of Oxford. Her research interests include multidimensional poverty measurement and analysis, welfare economics, the capability approach, and human development. Previously, she worked at the George Washington University, Harvard University, and the World Bank. She is a Fellow of the Academy of Social Sciences.

Sidonie Hadoux

Sidonie is a photographer and filmmaker based in Lille, France. After studying journalism, she studied photography at the Market Photo Workshop in Johannesburg, South Africa in 2016, and she is currently enrolled in an online mentorship with Through The Lens Collective, [also] based in Johannesburg. Her current work explores the notion of landscape in the post-industrial areas of Northern France, through the lens of a new ecofeminist visual imaginary. Sidonie photographs in response to the concept of female gaze, questioning the consequences of capitalist patriarchy on our lands and bodies.

Carl Anders Säfström

Carl Anders Säfström is a Professor (full) of Educational Research and Director of the Centre for Public Education and Pedagogy at Maynooth University Ireland. He is also an adjunct professor of Education at CRESI, University of Southern Australia. His latest book was published by Routledge in 2020 under the title "A Pedagogy of Equality in a Time of Unrest'. He is working on a manuscript for Springer, on "Education for Everyday Life. A Sophistical Practice of Teaching", which are to be published in early 2023. His interest is currently in exploring the place and role of improvisation in art, music and teaching.

Cecilia Sjöholm

Cecilia Sjöholm is professor of Aesthetics at Södertörn University. Her research is particularly focused on the relation between art and politics in contemporary culture. She has published extensively on aesthetics and critical theory. Her latest book, Through the Eyes of Descartes; Seeing, Thinking, Writing (with Marcia Cavalcante Schuback, forthcoming at Indiana University Press) looks at the relation between Descartes'thought and climate issues. She is one of the initiators of a new platform for research in the arts in times of climate change and societal transformation at Södertörn University.

Mats Bigert

Mats Bigert is a Swedish artist and one half of artist duo Bigert & Bergström. Bigert & Bergström have been collaborating since meeting at the Royal Institute of Art in Stockholm 1986. Since then B&B have done artworks and projects ranging from large-scale sculptures and installations to performance and film. Often with a conceptual edge, the core of their work is positioned between humanity, nature and technology. The duo is known to analyze scientific and social issues discussed in contemporary society, such as climate change or environmental sustainability. Between 1-19 June their large scale installation Tipping Point is shown at Galärparken on Djurgården as part of a collaboration with Liljevalchs konsthall, The institute for Future Studies and The Global Challenge Foundation.

Marie-Andrée Robitaille

Marie-Andrée Robitaille is an artist based in Sweden, currently doctoral candidate in performative and mediated practices at Stockholm University of the Arts (SKH). She has worked as a circus artist with Cirkus Cirkör among others and as a talent scout for Cirque du Soleil. From 2009 to 2018, she was an assistant professor and head of the Bachelor's program in Circus at SKH. In her previous artistic research projects, she investigated the representation of women in circus (Gynoïdes Project), sonic interactions (Sound of Circus), and sense-perception (Hidden Circus). In her doctoral project, "Circus as Practices of Hope", she focuses on alternative modes of composition as a method to support the emergence of posthuman practices in circus arts.

Emma Stenström

Emma Stenström is Associate Professor and Director of the Research Center for Arts, Business & Culture at Stockholm School of Economics (SSE). Her research concerns aesthetic, creative and innovative aspects of sustainable business, the intersection between arts and business, and the humanistic side of management. She has published hundreds of research-based articles, chapters, and columns. Beside her academic career, Emma has been a regular columnist in Dagens Industri since 2000.

Malena Britz

Malena Britz pro-Vice Chancellor at the Swedish Defence University. She holds a PhD from Stockholm University (2004) and is Associate Professor in Political Science at the Swedish Defence University. Her areas of research include different aspects of European security and defence policy, Europeanisation, and Nordic co-operation. She has studied different aspects of security policy from defence industry policy, development of EU security and defence, European states' participation in international operations, as well as international aspects of civil protection.

Tinna Joné

Tinna Joné, Assistant professor in documentary storytelling and responsible MA programs in Film and Media at SKH. Research about reality in the digital media landscape, exploring how new technology can support development towards more equal representation in the contemporary documentary narrative. 30 years professional experience in film and media. Directed documentary films for cinema in Sweden and abroad. Made investigative journalism, produced feminist radio and do art, performance and soundwalks in the public space.

Lars Strannegård

Lars Strannegård is the President of the Stockholm School of Economics and a professor of business administration with a focus on leadership. His research has dealt with issues of sustainability in large organizations, questions regarding branding, and how art and culture affect organizations. He is particularly interested in how higher academic activity is affected by digitization and how educational programs and environments can be designed in ways that consider the world we live in today. He is especially interested in how the logical-scientific and aesthetic forms of knowledge relate to each other.

Jakob Trollbäck

Jakob Trollbäck is the founder of the sustainability agency The New Division and the branding and design studio Trollbäck + Company. He is the main architect behind the communication language for the United Nation's 17 Global Goals, an ambitious and inspiring agenda for a better world by 2030. With offices in Stockholm and New York, he specializes in strategy and communication for sustainability.

Anna Enström

Anna Enström is a researcher, writer, and lecturer with a PhD in Aesthetics from Södertörn University, Stockholm. Her research is specialized on the aesthetic thought of Immanuel Kant, post-Kantian theories of art and contemporary critical theory. Her acclaimed and well received thesis is entitled Gemütstimmung, laughter and hypochondria: On aesthetic experience in Kant’s third Critique (2021) and among her most recent articles is “Kant’s globe – the critical philosophy, the lectures in physical geography and the sensibility of thought” in OEI magazine (2022).

Annick T.R. Wibben

Annick T.R. Wibben is Anna Lindh Professor for Gender, Peace & Security at the Swedish Defence University. Her research straddles critical security and military studies, peace studies, and feminist international relations. She is most frequently associated with Feminist Security Studies and Feminist Peace Research. Her publications include a monograph, Feminist Security Studies: A Narrative Approach (2011), and two edited volumes, Researching War: Feminist Methods, Ethics & Politics (2016) and Teaching Peace & War: Pedagogy & Curricula (with Amanda Donahoe, 2020).

Michel Östlund

Michel Östlund is an artist and film producer, living in Uppsala, Sweden. His work has a focus on existensiell issues and human rights. He express life, death, time, freedom speech with sculptures and paintings. He experiments with a blending of different disciplines into an interesting whole, where art, music, film, theater and architecture interact with each other. He works internationally. The last seven years his work has been around human rights and a mission to express what Human Rights is through art and culture. He has both educated and inspired next generation to understad the meaning of human rights with start at UN, New York to worldwide.

Robert Egnell

Robert Egnell (PhD London) is the Vice-Chancellor of the Swedish Defence University (SEDU) and a professor of leadership. Previous positions include Georgetown University, the Swedish Defence Research Agency, and the University of Dar es Salaam, Tanzania. Robert's research and expertise is best summarized with "the conduct and effectiveness of peace and stability operations". He has over the years has studied civil-military relations, counterinsurgency operations in Iraq and Afghanistan, peace support operations, state-building and security sector reform, gender in military operations, women in combat, as well as the connection between security and development.

Table of Contents

1. Sustainability and Science 1

1a. Theoretical approaches 1

Abstracts 2

Co-Producing 'The Future(s) We Want': Imaginaries of sustainability and collaborative knowledge-action models in Swedish sustainability and research policies 3

Dominant Leadership Styles: A multi-flex leadership styles blend towards educational effectiveness 4

Entangling the Security Paradox – moving beyond a normative construction of social sustainability and security 5

Human-nature Partnership – a normative framing for relational sustainability science? 6

Sustainability Science as Co-creative and Care-full Research Praxis 8

Full papers 9

Courage for Sustainable Development 10

Posters 22

1b. Research methods and methodologies 24

Abstracts 25

Circularity: Just Science Fiction? A science fiction prototype experience 26

How do the Ratings that Measure the Sustainability of Universities Integrate the Circular Economy? 27

LCA of Eco-efficient Techniques and Lifestyle: Case-study of a family unit with an agricultural holding 28

Full papers 29

Assessing the impact of Vehicle Development Process Improvement on Sustainable Development Goals 30

Enabling online backcasting: Experience and best practices from applying Gameful Backcasting (GAMEBACK) 5

Fostering Narratives through Arts-based Research 23

Posters 39

1c. Assessing sustainability 42

Abstracts 43

Assessing Stakeholder Engagement in Non-financial Reporting: Evidence from companies listed on the Italian stock exchange 44

Assessing the Impact of Circular Strategies at the Company Level: Design and validation of the SCEIA framework (Strategic Circular Economy Impact Assessment) 46

Drivers and Barriers to Organizational Learning in Non-Governmental Organizations contributing to the Sustainable Development Goals 47

The Pareto Checklist for Sustainable Development 48

Triple Loop Learning in Environmental Management Practice: Evidence of the RedES-CAR dissemination program 49

Using Meadows' Leverage Points as a Tool to Assess Effective Sustainability Impacts 50

Full papers **51**
Environmental Impact of Maritime Means of Transport: A case study of maintenance activities in ferries 52
Sustainability as Societal Value & Cultural Fact: A framework for value accounting 65
Posters **82**
2. Education **86**
2a. Provision, quality of and access to education **86**
Abstracts **87**
Advancing Care-full Scholarship within the Sustainability Sciences 88
Marrying Young: The surprising effect of education 89
The Role of Dilemmas and Paradoxes in Transdisciplinary Research Settings 90
Posters **91**
2b. Education for sustainability **93**
Abstracts **94**
Assessing the Development of Knowledge and Attitude for Sustainable Leadership through Simulation-based Learning: The preliminary findings 95
Education for Sustainability: The teaching of skills to achieve the sustainable development goals of the 2030 Agenda 96
Energy: A philosophy of practice 97
EUSTEPs MOOC: Leveraging ecological footprint for lifelong sustainability learning 97
Expanded Learning: Examples of embodied sustainability education practices 99
Exploring Accounting Educators' Perspectives on Sustainability: A Freirean critical pedagogic perspective 100
How to Achieve Reduction of Excessive Consumption? An educative approach with middle school students and their families 101
In Search of a Sustainable University: Lessons from a Brazilian case study 102
Marine Litter: Design, implementation, and evaluation of an educational intervention for young people to raise awareness and stimulate co-responsibility and sustainable behaviors 103
Philosophy in Nature. Walkshops as a pedagogical-didactical tool for planet proof education 104
Public Institutions for SDGs: Between didactic (participation teaching method) and social impact assessment 105
Relations between Universities and Recyclable Material Collectors: An analysis of the production of knowledge in action research 106
Short-term and Long-term Impact of Education for Sustainability on the Behaviour of Students 107
Teaching to Embrace Uncertainty – using SDGs as shared objects 108
The Impact of Teaching Engineering for Sustainability on Students. A comparative study on different levels of sustainability integration in University of Technology 109
The Regenerative Campus and Sustainable Wellbeing - an exploratory literature review on nature-based and transformative approaches in higher education institutions 110
The Educational Worldview Journey. A transformative learning tool for exploring, exchanging, and expanding perspectives in a world in crisis. 111

Universities Driving Sustainability: Exploring cross-cultural pathways to a circular economy of plastics on campus 112
Walkshops towards a Sustainable World. Teaching environmental philosophy in the woods 113
Full papers **114**
Creativity, Leadership and Education for Sustainability 115
Developing Social Sustainability with Circus-based Methods 133
Embedding Enterprise Focused Education for Sustainable Development: Lessons from undergraduate student experiences in product design 146
'Leading Change for Sustainability in Schools' Simulation: The training tool for educators in Vietnam 167
Socio-environmental Citizenship from the Perspective of University Social Responsibility. 178
Teeter Tru 186
University Social Responsibility experiences in Higher Education: Engaged research in Kyoto University 199
Posters **216**
2c. Beyond the Resilient Subject: Art, Education, and Imagination **219**
Abstracts **220**
A Blend of Indigenous and Non-indigenous Learning for Improved Educational Outcomes 221
A description of *Aesthetic Knowing*'s role in Ecologies of Courage, followed by some Educational Considerations 222
ARCHIPEDAGOGY: An Art Education for the Anthropocene 223
Dancing with the Other. A kinaesthetic and ethical shift from the egological to the ecological 224
Flying High, Falling Hard – Sustainability and presence in the performing arts 225
Reducing Carbon Footprints and Environmental Impact of Performing Arts Production 226
Rethinking Resilience in Environmental Education 227
The Potential of Arts-based Pedagogy to Face Imaginaries of the Anthropocene. A case study in Business School 228

Co-Producing 'The Future(s) We Want': Imaginaries of sustainability and collaborative knowledge-action models in Swedish sustainability and research policies

Tatiana Sokolova

Södertörn högskola, Stockholm, Sweden

Abstract

In the wake of the global sustainability agenda implementation, collaborative sustainability research has been actively endorsed at many institutional levels. Co-production of research and action, transdisciplinarity and actionable science have been incentivised and heavily invested in - seen as an 'epistemic imperative' for the politics of sustainability. However, neither sustainability nor collaborative research are sedimented phenomena; they are both infused with conflictual interpretations and take diverse conceptual and practical forms along the political and scientific spectra. Furthermore, the logics by which 'knowledge' and 'action' come together vary widely across disciplinary perspectives, contexts and actors. Evidence suggests that these conflicts between interpretations, logics and practices, if not acknowledged, potentially hinder the contribution of collaboration processes to 'sustainabilities'. However, there is also evidence that, if acknowledged and understood, these conflicts can promote reflexive sustainability governance by opening up political processes at various levels and creating spaces for change. This article examines how research policy supports the political imaginaries of sustainability in Sweden, and what implications the connections between the two may have for collaborative sustainability knowledge production. Empirically, the article analyses the overarching sustainability and research policies, focusing on the central documents produced by the government and public research financiers. The dominant metaphors and imaginaries employed by the documents, as well as the 'contamination' of the collaborative research policy with linear assumptions about knowledge-action connection, might enable research which strictly adheres to the dominant logics of efficiency, 'decoupling' environmental impacts from 'societal development', and production of knowledge as a commodity. Implementations of such policies are likely to reproduce the dominant sociotechnical imaginaries, precluding re-imaginings of democratic sustainabilities.

Dominant Leadership Styles: A multi-flex leadership styles blend towards educational effectiveness

Dr. Mani Man Singh Rajbhandari

St. Xavier's College, Maitighar, Nepal

Abstract

The purpose of this study was to explore the dominant leadership styles among the four traditional leadership styles 1) Autocratic, 2) Bureaucratic, 3) Democratic and 4) Laissez –Faire/Free rein/Abdicratic. Within these four traditional leadership styles, this study attempts to explore the dominant leadership styles through a multi-flex leadership style blends. Leadership is a core component of any organization that enhances the sustainability and development. This is achieved through application of appropriate leadership styles within the organization to sustain the employees wellbeing and concern towards the mindfulness. Although all leadership styles discussed in this study is appropriate but the fit appropriateness of leadership styles depends on contextual settings and followers domain. Therefore, the wellness, wellbeing and the mindfulness of employees and generating the conducive organizational climate can in addition contribute towards sustainability and development of the strategies, policies and organization as a whole.

A conceptual theoretical construction amongst the leadership styles were blended to categories while arriving at the multi-flex leadership styles. Thorough investigations were made of these four traditional leadership styles towards blending each style with another to represent various multi-flex leadership styles.

This exploration finding generated six multi-flex leadership styles with the blending of each traditional leadership styles with one another. Moreover, blending three or more leadership styles produces lesser multi-flex leadership styles reflecting towards dominancy of leadership styles. A dominant leadership styles were predetermined by the three factors the context, followership domain and the leader. Any two leadership styles can generate multi-flex leadership styles (higher applicability of one styles and lesser to another or vice versa). Thus, leadership applicability of these styles generates twelve sets of multi-flex leadership styles. Not all of these leadership multi-flex blends can produces reliability to contextual settings or to the followership domain. Therefore, appropriateness of leadership blend is an utmost pivotal aspect that a leader must contain towards understand both the demand from the context, the followership needs and the capability to release the one dominancy style with another. The COVID-19 pandemic instigated the need for change, thus it necessitated a change in leader style flexibility and tendencies towards mobility from style-fix to style-flex. Higher applicability of any one leadership style with another being lesser applicability within the multi-flex blend that fit the context and matches the followership domain can/may be considered a dominant leadership style. Thus, a higher applicability of any one leadership style with the multi-flex blend being lesser applicability of another style blend that fit the context and matches the followership domain can/may be considered as a dominant leadership style.

Entangling the Security Paradox – moving beyond a normative construction of social sustainability and security

Ms Irja Malmio

Swedish Defence University, Stockholm, Sweden

Abstract

This paper uses a deconstructive approach to analyze the "messy" relationship between social sustainability and the concept of security, while also discussing the limitations of binary thinking that is mediated by a normative framework. When examining crises and security issues, social sustainability can be described as a key component, as areas that are prioritized items on the agenda for the "western liberal" defense sector, such as maintaining democratic values and strengthening society's overall ability to deal with stress, bears a deep association with goals for social sustainability. This conjunction, however, also involves a paradox where security sometimes imply an obstruction of civil emancipation principles, therefore presenting a possible trade off situation between social sustainability and security. A paradox perspective on this relationship acknowledges a core value in military strategy that is opposed to social sustainability due to an embedded power dimension which supports the idea of an aggressor, a potential victim and someone or something that can neutralize the threat, thus opposing the idea of the peoples right of autonomy, emancipation and self-government. Furthermore, the ambiguous nature of the concept of security bolsters this paradox and solidifies an understanding of sustainability and security as insurmountable to merge.The overall idea present in the co-production perspective is that security and sustainability not only are interrelated but also co-contingent, in a sense where one cannot exist without the other. The co-production perspective also cultivate a view on development and security as intimately connected, In accordance with this proposition, this paper identifies a need to reformulate the view on security, development, and the liberal idea of "protection". Another point of departure is to treat paradoxical logics, and messy research areas, not as a source of conflict, but as a starting point for a deepened understanding of the interdependence of pluralistic values, that promotes sustainability and democratic principles.Therefore, a suggestion is to move beyond binary thinking and normative evaluation and instead treat the security – sustainability nexus as a system composed of many different parts, which is not in opposition, but are co-constructive and interdependent phenomenon's that can deepen our understanding for the social dimension of security as well as sustainability.

Human-nature Partnership – a normative framing for relational sustainability science?

Dr. Martina Artmann[1], Philip Harms[2], Mabel Killinger[2], Susanne Müller[2]

[1]Leibniz Institute of Ecological Urban and Regional Development (IOER), Dresden, Germany. [2]Leibniz Institute of Ecological Urban and Regional Development, Dresden, Germany

Abstract

Despite scientific and political efforts to respond to today's social-ecological crisis, challenges such as climate change, biodiversity loss as well as social and environmental injustice are intensifying. For addressing "deep" leverage points for transformational change, sustainability research sees the need to engage with paradigms and worldviews that separate humans from nature. Such dichotomies are also mirrored in current scientific concepts such as ecosystem services emphasizing the instrumental values of nonhuman nature and building on a human-centered worldview. As an alternative normative framing of human-nature relations overcoming this anthropocentric paradigm, this talk will reflect upon the concept of human-nature partnership for sustainability science. The theoretical grounding of the concept will be nourished by the resonance theory by Hartmut Rosa.

This social science theory was developed to provide a solution for acceleration-oriented modern societies characterized by an increasing alienation in daily life such as from nature. Resonance is to be understood as a counter-term of mute relations and describes responsive relations between humans and the world strengthening in normative terms a good life. Basic preconditions of resonance are its unavailability and that the relating entities are speaking with an own voice. By translating these ideas into a concept of human-nature partnership for sustainability science, the talk will argue that it needs a shift from mute to resonating human-nature relations. Thus, mute human-nature relations are characterized by making nonhuman nature available such as through resource depletion thereby denying her agency, intelligence, and sentience. In contrast, resonating human-nature relations are characterized by a material and immaterial reciprocity and respecting nature´s unavailability and dignity with a morality of care and justice. Such relational qualities can be understood as a human-nature partnership, taking into account that both human and nonhuman nature have the right to flourish. Human-nature partnerships are characterized by respecting that both sides as well as their relations hold intrinsic value and are related to each other through a reciprocity exchange of giving and taking while neglecting dominance and hierarchy.

How the conceptual framing of human-nature partnership can feed into a real-life context will be discussed by focusing on urban human-nature relations from various perspectives. Collective urban human-nature partnership will reflect about the role of urban planning as a value-based collective endeavour. In this regard, the talk with shed light on moral implications of urban planning for shaping human-nature relations and possible tensions with currently prevailing planning approaches. Another focus will be laid on individual human-nature partnerships in cities by enriching the resonance theory with insights from indigenous ontologies, mindfulness research, and spiritual rituals. By doing so, some first insights into the development of a practical relational tool will be presented. As a third example, human-food relations will be discussed as an individual but also collectively shaped relational quality with high potential implications for sustainable transformations towards human-nature partnerships. In the end of the talk, this contribution will make up some open questions for future inter- and transdisciplinary research that can strengthen fundamental shifts towards human-nature partnerships in cities and beyond.

Sustainability Science as Co-creative and Care-full Research Praxis

Professor Alex Franklin

Coventry University, Coventry, United Kingdom

Abstract

In this presentation, drawing on a conceptual frame of a feminist ethics of care, I argue for the co-creative potential of research to be more actively and reflexively nurtured throughout the sustainability sciences. In doing so I pay particular attention to the value of plural knowledges, to socially inclusive forms of engaged research praxis and also to research as a relational and embodied pursuit. My aim is to stimulate further reflection and debate on the role of 'co-creativity' – but also, the sustainability sciences more broadly - in enabling transformative sustainability agendas. A key guiding question which I consider during the presentation is how co-creative research practice, as a generative process, can best be used to support the emergence of alternative – potentially even transformative – ways of being in the world? The term co-creativity is understood here as encompassing both individual methods and overarching research approaches that, through action and reflection, stimulate alternative understandings of why and how things are, and how they could be. In drawing on feminist care theory I make a case for the importance of researching 'with' as a core principle of sustainability science scholarship. Supported by a number of illustrative examples (sourced primarily from my own recent experience of co-ordinating a four-year Marie Curie Innovative Training Network) I evidence how a retained openness for the unknown and unforeseen can act as a golden thread for a simultaneously rigorous and impactful research methodology; an approach which I argue can, in turn, also contribute to the on-going pursuit of more 'care-full' sustainability scholarship.

Courage for Sustainable Development

A virtue ethics perspective

Pauline PICOT[1], Bertrand GUILLAUME[2]

[1] *University of Technology of Troyes, pauline.picot@utt.fr*
[2] *University of Technology of Troyes, bertrand.guillaume@utt.fr*

Abstract

The whole Sustainable Development Goals (SDG) intends to orientate action toward a desirable, valuable future. In this way, their pursuit falls within the scope of normative ethics as part of axiology, which is the philosophy of values. If the axiology of the Anthropocene was to be studied, it would without a doubt underline the weight of science, which produced the knowledge at the origin of the "Anthropocene" proposal, but stands also as a powerful analysis tool as well as an assistant toward decision-making. However, sustainable challenges do not only stand as scientific issues, they imply to develop new ways of living thus entail social and cultural dimensions. That is why a discussion about axiology in the Anthropocene must go beyond the value and virtue of science. In this paper, we raise the need for other "virtues" (moral characters) complementary to science and, in particular, we explore the problem of "courage" in the face of the Anthropocene and sustainability challenges. We first discuss "virtues" as an approach to normative ethics before and beyond deontology (rules of actions) and consequentialism (effects of actions). In ancient Greek, "virtue" is related to "excellence", it is a quest toward self-improvement intimately linked to the "*logos*", the rational thinking. In this sense, we can understand the linkage of virtue to knowledge and knowledge production, but virtue is also a matter of practice, it is learned by the daily exercise of rational thinking in the way we behave. We then review the substantive meanings of "courage" considered as a cardinal virtue. Indeed, Plato identified it as one of the four cardinal virtues of humans, to be adjoined notably with wisdom, the perfection of knowledge. Beyond Plato, we intend to consider the evolution of the meanings of "courage" today in contrast with ancient texts, and apply such a philosophical investigation to the threats of current un-sustainable development and planetary crisis. We finally discuss our results, and conclude in the framework of the conference regarding the potential of the "courage" virtue in for scientists for both analysis and action in seeking for sustainable development. Indeed, regarding the SDG, we believe that courage is most relevant in the fight against inequalities (SDG 10), the fight against biodiversity loss (14-15), the shift toward responsible consumption-production (12) and the fight against climate change (13): all of these objectives together ask for the courage to face our deep dependence to nature, the planetary limits and re-interrogate our acts, and projected futures on that basis.

Keywords: Courage, Science, Virtue Ethics, Anthropocene

1. Introduction

For at least a decade, literature has been developing that defends the relevance of a reinvestment of virtue ethics in the context of the Anthropocene (for instance: di Paola [2015]; Goffi [2009]; Pelluchon [2017]). This model of ethics takes its roots in Greek ancient philosophy, that is in a political, social, and even climatic context that seems far from ours. The reasons for this "return to roots" could then be interrogated.

The Anthropocene is first of all a scientific reality, its denomination comes from and echoes the geological description of time: it designates a rupture with the Holocene. It is an unprecedented phenomenon, and it constitutes in this sense a new representation of the world that is constituted, documented by scientists from various disciplines. However, this new reality points to our ways of living, acting as destructive and requires a shift, an engagement into a transition toward sustainable ways of inhabiting the world. Sustainability then demands an evolution of our cultures, of our values and in consequence falls into the scope of ethics as part of axiology, the philosophy of values. We wish to warn the reader that this paper has been written by two researchers from a western high-income country and that, consequently, we write from this point of view.

In this perspective, virtue ethics is relevant: as we will later develop, virtue ethics is primarily concerned with the individual and her progress thanks to the culture of virtues. It thus allows thinking the evolution, the transformation (Pelluchon, 2017) of the individual human being in accordance with ecological issues that we are facing.

Because the required transition is global, we support that sciences are also concerned. Guillaume (2021) identifies three challenges to knowledge in the Anthropocene: the continuing of its development in a move toward unification, that is, disciplines are not to remain isolated from one another; the implementation of knowledge into politics and ethics; its appropriation in culture. Scientific practices, relationships of sciences to society and cultures as they are today established are to be subject to transformation. In that perspective, it seems relevant to us to mobilize virtue ethics in a reflection on the figure of the scientist in the Anthropocene.

We choose in particular to focus on the virtue of courage. On the one hand, this choice is motivated by a rather straightforward and shared intuition: it requires courage to face the scientific reality of the ecological crisis and to put into question our ways of living. On the other hand, courage as a virtue has a long history in philosophy, coming back at least to Plato. This allows us to position our argument in continuity but also in contrast to this philosophical inheritance that is in an evolving line which echoes the understanding of sustainability as an evolution, a transformation.

We choose moreover to discuss courage rather than fortitude. Courage and fortitude have similar meanings, but fortitude primarily concerns mental strength, it firstly refers to the internal dispositions of the subject. Yet, although internal dispositions are essential for the development of virtues, these last are firstly to be observed in situations, in action, in behaviors. In this sense, we prefer to discuss courage rather than fortitude in order not to have this accent on the mental state over action.

In the following section, we first position virtue ethics as being before and beyond the other main models of ethics (deontology and consequentialism) and support its particular relevance in the Anthropocene. In section 3, we elaborate our conception of courage as a virtue. We discuss in section 4 the place of courage in sciences and finally, in section 5 we justify the importance of virtue ethics for scientists in the Anthropocene.

2. Positioning of the paper: Virtue Ethics before and beyond Deontology and Consequentialism

The origin of virtue ethics leads us back to the Ancient Greek philosophical tradition. The Greek term for virtue "*arete*" can as well be translated into "excellence" (Pellegrin, 2016): an excellence sought in anyone's behavior. The expression of virtue is thus first in situations: a virtuous agent would be recognized for her habit to act virtuously. As a habit, virtue is to be learned, it is commonly considered that every human being possesses the seeds of virtue and that they are to be cultivated by daily exercise, by moral education. A virtuous behavior requires good use of practical wisdom. In this sense, even if the virtuous agent acquires virtuous behavior as a habit, the exercise of virtue demands engaging in reasoning, in an evaluation of the situation. It is not pure instinct. Practical wisdom, *phronesis* in Greek, also understood as prudence in action, is described in Aristotle's texts as the right deliberation (Pellegrin, 2016). This deliberation conditions the rational choice regarding the way to act. The *phronesis* is an intellectual virtue and, by its use, is the condition for the other virtues. Virtuous actions according to Aristotle are always a right measure, each virtue being a mean between two extremes (Aristotle, 2014). As an illustration and to anticipate our next argument, courage is the mean between cowardice and rashness, respectively lack and excess of courage. However, each virtue expresses the opposite of lack and excess, thus virtue as a mean does not express mere moderation in Aristotle's views but is an extreme as well. This translates the difficulty to reach virtue.

Acting appropriately is nevertheless not enough to act virtuously. The action has to be done with the right motivation: someone who acts for fear of punishment or in seeking personal reward is not virtuous. Virtuous action is recognized in the absence of regret and of any kind of reluctance in the decision of doing it. In consequence, virtuous actions are not limited to an insensitive rational choice, but ask for a full affective investment of the individual. This lack of regret, of difficulty in the resolving to act makes place for *eudaimonia*, happiness, the true aim of any human life. An affective difficulty in the ethical act indicates that the subject is not yet fully virtuous, but, again, it is by

practicing that the habit will be developed and make the action easier. The culture of virtue joins the accomplishment of any human: happiness (Annas, 2007).

Virtue, as singular, actually gathers several virtues that are linked one to another, and that may ever be conditioned one to another as the previous example of the *phronesis* that conditions other virtues. We will not subscribe here to a given and fixed list of virtues. On the contrary, we will assume that, over time, space, and cultures, diverse conceptions of virtues have existed. In that perspective, the number of identified and/or identifiable virtues may have evolved along with, obviously, their denominations.

Plato, for instance, identifies four cardinal virtues: temperance (*sophrosyne* - self-control, mastering of pleasures), courage (*andreia* - capacity to judge formidable threats), wisdom (*sophia* - excellence of knowledge), justice (*dike* - the perfect ordering of different virtues in a whole) (Brisson & Pradeau, 2016; Plato, 1966).

The example of Plato allows us to introduce the link between virtue ethics and politics. Indeed, the parallelism is direct between the virtues of a single human and the virtues of the City (Plato, 1966). The ideal Republic that Plato imagines is organized in three orders, each of them fulfilling a specific function: laborers, Guardians, and the governing class (the best among the Guardians). Temperance in the City is reached when the wisest class is governing the others. Courage is to be mastered by the Guardians that aim to protect the City and to maintain the law within it. Wisdom is associated with the governing class and the Guardians in the deliberation toward political action. The last virtue, justice, is positioned as resulting from the correct articulation of the three orders between them, just as three organs in the same body.

We argue in this article that virtue ethics goes before and beyond the two other main ethics models: deontology and consequentialism. The first one of these two considers an action as ethical if it complies with a set of rights and duties that can be defined a priori, out of any specific situation; whereas the second one positions the ethical choice as the result of a calculation that focuses on the expected effect of actions and compares them.

Ethics virtue goes before these two other models of ethics chronologically, but we argue that it precedes them as well in the sense that virtue can be the fundamental of ethics without needing to refer to a set of rights or to a calculation mode that would be more fundamental. We follow here the argument of Kawall (2017) who takes a non-controversial example of a wrong action: torturing puppies. He aims to explain why this is wrong thanks to virtues only. He reasons that it is wrong because of the formidable pain that it would inflict on them, pain that would move the virtuous agent thanks, in particular, to its virtue of compassion. For this reason, the virtuous would disapprove of the act, and in reason of this disapprobation, torturing puppies is wrong. Then, it could be argued that Goodness and Wrongness are arbitrary, only relying on subjective judgment rather than objective properties. To answer this counter-argument, Kawall introduces an analogy between the judgment of a virtuous and our visual perception: even if this one is dependent on the way our brain interprets the image it received, it fundamentally depends as well on the human eye, on our perceptive apparatus. This point refers to the distinction between innate and acquired at the heart of virtue ethics: virtue is cultivated and is thus acquired for a part, but it also comprises a part of innate, each

all have a certain sense of compassion. This clarifies as well how the praised virtues may change from one cultural context to another without resulting in a complete relativization of virtue ethics.

Moreover, we argue that these parts of innate and acquired, this dimension of the culture of the virtues makes virtue ethics particularly relevant in the context of the transition toward sustainability. This argument positions virtue ethics beyond deontology and consequentialism. Indeed, the ecological crisis calls into question our ways of living and with them, not less than our way to inhabit this planet and our relationship with the world. In that sense, an ecological transition is inseparable from a cultural dimension. Because virtue is cultivated, it allows for the description of a "process of self-transformation" (Pelluchon, 2017) which starts from human, in its corporeality, and with it from its relationship to the world. Furthermore, this transformation is complete in the sense that it engages our reasoning as much as our affects. This affective dimension of sustainability is also highlighted in the ecosophy T of Naess (Pelluchon, 2017) and by Albrecht in the need to answer solastalgia, that is pain while seeing our home, close environment transformed, destroyed (Albrecht et al., 2007).

A virtuous action demands as much to deliberate properly as a full emotional investment in the action. Pelluchon gives the example of the learning of the aesthetic experience of nature: the knowledge of our links, of our dependence on nature contributes to it as well as the sensory experience of it. These two dimensions nourish each other.

In contrast, the main models of environmental ethics do not allow describing such a transformation of the individual. Indeed, biocentrism can be considered, depending on the formulation, as a form of deontology (deriving rules from the acknowledgment of a right to live of every being - see for example Taylor [1986]) or of consequentialism (seeking for maximizing the satisfaction of biological needs - see Attfield [1994]) (Maris, 2010). Ecocentrism gives a non-instrumental value to ecosystems or species, thus it departs from nature and then addresses the individual in terms of moral obligations (Pelluchon, 2017).

3. Substantive meanings of "courage" as a cardinal virtue

As mentioned previously, courage is identified as a virtue since, at least, Plato. In his works and notably in the *Republic*, the paradigmatic *andreia* (courage) is the *andreia* of the guardians, in charge of maintaining public order and above all protecting the *polis* (city) between external threats (Plato, 1966; Zavaliy, 2020b). Thus, the *andreia* concerns firstly the courage of the soldier facing an enemy, that is facing a potential death, and who still holds his position and fights for his City. The *andreia* is thus political (*politikos*). Like any virtue, courage is to be cultivated and Plato develops widely the training of guardians, this allowing us for understanding the role of reasoning and the activity of affects in the exercise of courage. Indeed, cultivating courage consists in a culture of the *thumos*, the anger necessary to engage in risky behavior and thus necessary for courage (Plato, 1966; Zavaliy, 2020b). The *thumos* also refers to a certain ferocity and animality. Its culture consists in the channeling by reason and in its reorientation toward the interest of the City: any personal interest must disappear in the motivation of the guardians. The only threats that are to be feared and in face of whom the *thumos* must be felt are the threats that go against the interests of the City. The reason intervenes in the establishment of the knowledge of the situation, in the appreciation of the faced

philosopher describes courage as the right mean, the right measure between cowardice and rashness, between fear and confidence, this right measure being informed by the knowledge of the situation (Aristotle, 2014; Zavaliy, 2020a). Courage according to these two authors is thus not the absence of fear. Besides, Aristotle recognizes as well the intervention of the *thumos* in engaging in courageous action (following Zavaliy [2020a] in his interpretation of Aristotle [2014], 1117a4-6). However, contrary to Plato who does not forbid the existence of courage in other situations than military fight, Aristotle reduces the *andreia* to this single situation, to the courage to face a noble death (Zavaliy, 2020a, 2020b). Through this criterion of nobility, the predominance of the general interest over personal interest can be understood. A difficulty that appears in consequence of this statement is however the relationship between the virtue of courage and *eudaimonia*: how does risking his life at fighting contribute to a happy life? A plausible answer is that the aimed *eudaimonia* is not the one of the individual but the one of the City, or rather the maintaining of the City in order to provide to its inhabitants the conditions to reach *eudaimonia* (Zavaliy, 2020a).

As previously argued, virtue ethics gives space for cultural variations through, for instance, differences in the identification of virtues. For this reason, the descriptions of Plato and Aristotle would be considered situated in their epoch. As such, we will assume that the predominance of courage as military courage echoes the mythical context of that time. Aristotle's account of courage can even be read as an attempt to bring back the virtue of courage to the Homeric conception of courage (even if he refutes that any true example of courage can be found in Homeric texts) (Zavaliy, 2020a). Moreover, we may suggest that the particular importance of the military courage in Plato's texts is called by the aim that the philosopher is pursuing: the description of courage is notably elaborated in the *Republic*, which is in an effort for imagining a just, ideal Republic.

In consequence, we will consider that courage as we understand it today has evolved since its Greek preceding *andreia* without negating the heritage of this one in current thought. To defend this argument, we will refer to examples that are recognized in popular culture as expressing courage.

We will retain from the above that courage always implies a *facing*: for the Antiques, it consisted essentially in facing the imminent possibility of death. We argue that this point is too restrictive for the common understanding of courage. The courage in face of physical danger is of course still recognized as such (we can think for example about the fireman in face of fire) but we would as well introduce a political courage that does not imply an enemy exterior to the City, in a more contemporary understanding, exterior to society. As a first example, we will think of the famous act of resistance of Rosa Parks, done despite the risked sentence. In general, the fight of the Black people for the equality of rights between Black and White people offers an example of a political fight intern to a State risked despite physical danger.

Another example to which we will refer is the one of Simone Veil, a French politician who carried the law for the legalization of abortion in France. This political fight remained famous for its success, but as well for the violence of the insults and threats that she had to endure. Demonstrating courage is not just exposing herself to a physical danger, but also to a psychological one.

In these different examples, it can be noticed that a characteristic that remains common to the Greek

than the personal interest and concerns a defense of, a demand for justice or for Good. Courageous action is altruistic. In consequence, courage implies as well reasoning, it is an act or a series of acts guided, oriented by reason.

Because it implies a danger, an exposure to it, and to some extent suffering from it, the subject cannot keep an affective distance to her action, this last cannot be just cold insensitive rationality. The agent is necessarily affected and her affects will necessarily intervene in her engagement in action (we could remember the Greek *thumos*, more generally a discussion could be led on the question of the affects leading the agent to engage in risky action). A courageous action constitutes a full experience, implying in dialogue reason and affects.

Among these affects, but without reducing them to it, is of course to be found fear. In that sense, as courage demands to channel and overcome her fear, it consists as well of an internal facing. To fear could be adjoined as well the idea that courage can be found in facing anxiety. Whereas fear has a defined and immediate object, we distinguish anxiety by a worry about the future. Indeed, anxiety accompanies the perception of a threat whose actual realization, the situations that it will create, are rather unpredictable and beyond the control of the subject (Anderson, 2004). Facing anxiety means thus facing indetermination, uncertainty, a kind of unknown.

4. Courage Virtue and Sciences

Due to their seeking for producing knowledge, *known*, scientists are logically dealing with unknown, with uncertain. Making science is even seeking for this uncertain, in the sense of seeking for widening the field of the known, but as well in the sense of the culture of doubt, of the (re)questioning and (re)testing of hypotheses, of what is thought to be known.

In line with that perspective, the epistemologist Bachelard describes the scientific mind as a constantly fighting mind, in a violent effort to overcome “epistemological obstacles”, among them: opinion based on observation (opposed to experimentation) but as well the abusive will to generalize, to make system. The scientific mind progresses then by rupture, in destroying and reorganizing knowledge. In that sense, the scientific mind must always remain open to newness, to this fight (Bachelard, 1996; Bontems, 2010).

We would interpret this position of the scientist as a perpetual seeking for the right amount of confidence in her result, more generally in the current corpus of science as she knows it. This position is finally the one of fleeing in front of the tempting comfort that would offer a complete trust in sciences as established.

In counterweight and by this open-mindedness, this acceptance of instability, of an *uncertain*, we would suggest that practicing science has to do with anxiety and in the end with certain courage. We have however stated that courage as a virtue is a political courage, at least an altruistic courage. Yet, considering that sciences are among all an affair of truth, they do not immediately appear as seeking for good.

Research in technology offers nonetheless multiple (ancient as well as contemporary) examples of a direct relationship between scientific activity and politics, understood in the large sense of what relates to the *polis*, the Greek City-state, or the society. We understand here “technology” in the sense that its etymology

to the concrete example of the "Internet of Things" (IoT), a growing economic sector, supporting deep transformations of our societies and sector in which scientific research participates actively: a quick search on Scopus gives almost 25,000 scientific articles mentioning in their title the expression "Internet of Things". However, the various devices and uses that this area concerns raise important privacy and security issues, as summarized by Karale (2021). They are thus far to be ethically or politically neutral. It can be added that the digital sector to which IoT is related takes its part in the ongoing ecological crisis. Estimating the carbon footprint of the global digital sector is complex and always subject to uncertainty, but it can be assessed between 1.1 to 1.4 GtCO2e in 2020, which represents 2-2,5 times the global footprint of France (figures from Roussilhe [2021] and *Estimation de l'empreinte carbone de 1995 à 2020* [2021]). Social issues can as well be pointed to, the Ph.D. thesis of Marquet (2019) illustrates it: he studied the controversy and issues caused by the installation of data centers lived by the inhabitants of a city at the North of Paris.

As a distant example, mining sciences can be mentioned as they combined fundamental sciences and research with industrial technical issues along with research toward new marketable products in the 18th century in Prussia (Klein, 2020). Klein, who studied these scientific activities among others in the same area and period, concludes as follows and we align ourselves with her conclusion: whereas the "technosciences" are often thought as new and specific to the 20th century, they are actually inscribed in a much longer history of dialogue and co-evolution of sciences and industry, of scientific and technological knowledge, of sciences and economic interests (Klein, 2020).

In addition, we would assume that fundamental sciences cannot be separated from politics either. Indeed, their development is framed by institutions whose funding and organization depend on the political and societal context (the history and role in the development of sciences of the learned societies such as the Royal Society can be mentioned to support this argument).

We would conclude, then, that sciences, in their practices, are a transformative force of society and in that perspective cannot be separated from the political. On that conclusion and having suggested that scientific practice can have to do with anxiety and confidence, we will argue in the next section that the Anthropocene challenges the scientists in its behavior and practice and requires from her culture and exercise of courage understood as a virtue.

5. Discussion: Courage Virtue and Sciences in the Anthropocene

We support that sciences nourish the Anthropocene in at least three ways:

they instruct its scientific reality: the term "Anthropocene" itself originates from a scientist.
Its factual reality is constructed by scientific research, the IPCC (Intergovernmental Panel on Climate Change) or the IPBES (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services) can be mentioned as obvious examples;

research activities in themselves actively participate in this reality by their ecological impact: travels for conferences are an obvious and on-the-point example, but more generally, it can be underlined that research activities participate in the global ecological footprint of the university campus (as an example see Genta et

al. [2022]) and indirectly to ecological footprints of various sectors (the IoT example can be mentioned again here);

in consequence of the two preceding points, sciences instruct our way of inhabiting the world, they are intrinsically linked to our representations, our ways of thinking, acting, and suffering in this world. Yet, it is precisely these ways of inhabiting the world that are pointed as destructive. The required cultural transformation thus comprises a transformation of sciences, of our ways of making them, of their relation and status in the *polis*.

Moreover, we argue that facing this transformation issue, reacting to these three points requires from the scientist a courage that can be considered as relevant of virtue.

The first point obviously implies that a scientific courage in the Anthropocene consists in facing the produced scientific reality. Eco-anxiety is today a widely documented phenomenon (Panu, 2020) and we suggest that this verifies our previously argued idea of a link between scientific activity and anxiety. For a scientist, this indicates as well a collapse of the distance between subject and object in the researcher position: she cannot maintain a distance to the studied object but is impacted, *affected* by it. This can be interpreted as an engagement in an experience in which (scientific) reasoning and affects dialogue.

A first courage thus lies in the reception of this experience, in the assumption of this collapse between object and subject, and, as a consequence, in engaging in re-interrogating our ways of making sciences, in our scientific practices. This means to face, to overcome several cognitive dissonances. Engaging into and cultivating an interrogating position and beyond it a transformation constitutes then a courage that answers, that faces our second point above.

It is to be noticed that the Anthropocene being a reality that goes beyond the individual, we assume that such an engagement is political and thus in coherence with the conception of the courage described previously.

The re-interrogation of scientific practices includes a re-interrogation of the way scientific results are disseminated. We can only observe the gap between the scientific knowledge we have and the absence of inflection in the trajectories of our societies. This would suggest that scientific knowledge is not enough to induce a complete self-transformation as required in the context of the Anthropocene. We suggest that to fill this gap, to increase its transformative power, the dissemination of sciences cannot limit itself to cold rational speeches, to the position of the scientist standing on a stage in front of her public, but rather take the form of a shared experience. We would like then to address to the reader this open question: How to make the sciences of the Anthropocene a shared experience?

For our part, we consider that a possible answer may be found in the development of interdisciplinary and transdisciplinary research. Interdisciplinarity is not new, however, dissonance can be observed between a disciplinary tradition, organization, and specialization in science on the one hand and recurrent calls and praise for interdisciplinarity on the other (Andersen, 2016). Besides, both examples of research in technology from the previous section are as well examples of interdisciplinarity. In consequence, we do not

acknowledgment and seeking for interdisciplinarity as necessary in order neither to confine research in sustainability to a single discipline nor to confine it in several separate ones. Natural sciences and human sciences have been constituted respectively in excluding humans for the first one and nature for the other (Bonneuil & Fressoz, 2016). However, the Anthropocene designates the overflowing of one of these categories into the other: humanity has become a geological force, and nature in crisis collides with our cultures. In consequence, understanding the Anthropocene as a phenomenon of the natural sciences requires integrating humans into models; understanding the Anthropocene as cultural requires taking into account nature, an environment that is not anymore a mere passive exteriority. In that perspective, the Anthropocene and with it sustainability cannot be grasped by established disciplines. They require overflowing.

We distinguish transdisciplinarity from interdisciplinarity by the strong link of non-academic actors that implies the first one, whereas the second one was considered as internal to the scientific domain in the argumentation above.

We subscribe to the principles of transdisciplinarity as described by Scholz (2020). They characterize transdisciplinarity by a strong collaboration between sciences and stakeholders from society in a position of equality and mutual learning. Scholz argues further that transdisciplinary is necessary to achieve sustainability due to the complexity of the issues to be faced and due to the different societal interests that are engaged in them and add to the complexity. In that perspective, it is difficult for a single community of scientists to pretend to be able to get a complete and comprehensive view of the issue at stake without engaging with the different stakeholders. This implies for the scientist to cultivate open-mindedness and readiness to combine her knowledge and practices with non-scientific knowledge and practices.

Interdisciplinarity and transdisciplinarity thus both demand open-mindedness to the scientist, demand her to face instability, (re)newing. This position echoes the description of the scientific mind of Bachelard that we have interpreted as a form of courage.

By this intellectual openness and by their definitions, interdisciplinarity and transdisciplinarity must result in new and plural knowledge and forms of knowledge, in new and plural ways of making sciences. Such transformations of sciences cannot but impact our ways of representing, acting, and inhabiting the world. In this sense, we answer here the third of the points we identified at the beginning of this section.

6. Conclusion

Acting virtuously supposes to act appropriately and for the right motive. In this sense, the virtuous action requires the mobilization of reasoning for the determination of the right way to act and an emotional engagement: the real virtuous action is not undertaken reluctantly or in seeking personal profit. Courage as a virtue is primarily in Greek philosophy the courage of the warrior protecting his City. We argued that such a conception of courage is too restrictive for our time and proposed to understand virtuous courage as the altruistic action to choose to expose herself to danger, to physical or psychological suffering in seeking a Good or a justice that goes beyond her personal interest. Courage does not imply the absence of fear or anxiety but overcoming them for the right motive. We have suggested that scientists, by cultivating criticism and doubt in their refusal of excessive confidence in the current state of their knowledge, express the qualities

the Anthropocene, this thesis is verified by the scientific reality itself: by the threat that it represents and the demand for transformation that it constitutes. We suggest then that a first scientific courage lies in facing this reality. This means not to consider this last anymore as an observed distant scientific object but to receive it as impacting us as subjects. That implies abandoning an affective distance toward it, thus receiving it as a lived experience that makes dialogue reason and emotions. Courage then lies in engaging in an effort of transition. Indeed, sciences participate in the Anthropocene in documenting its reality but also in making this reality and in nourishing more broadly our representations of the world. They are thus part of the transition toward sustainability and that requires from the scientist an openness for re-organization of sciences, their practices, their relationships to society, that is a readiness to face newness and uncertain. There lies the second courage to be cultivated from our point of view. In this sense, we suggest that a relevant question in the perspective of the transition of sciences toward sustainability is not only how to share scientific knowledge of the Anthropocene but how to share the experience of it (experience understood as implying both reason and affects in the reception of knowledge). We argue from our point of view that interdisciplinarity and transdisciplinarity may be part of the possible answers.

Biodiversity viewed from three sustainability models, and two systems ecology textbooks

1. Intro

Biodiversity is identified as one of the major environmental sustainability issues, alongside with global warming, and is often defined including the three levels genes, species, and landscape.

In this paper the concept of biodiversity is viewed from five different angles, see sections 2.1 to 2.5.

2.1 The Daly model

Herman Daly's model of a full or empty world show a finite world of 1) sources for energy and natural resources, and 2) so-called sink capacity, the biosphere's ability to assimilate our wastes in solid, liquid, and gaseous form (Figure 2). Biodiversity, on the resource side, is a diversity of organisms for the economy to choose from; on the sink side a biodiversity of, mainly, microorganisms that enhance the decomposing capacity to assimilate more types of solid, liquid, and gaseous waste.

A difference between biodiversity and other resources are, however, that the biodiversity in itself is not used up. The biodiversity can be seen as working similar to a catalyzer, building structure by converting resources of different types to goods and services in society.

2.2 The Natural Step

The model behind The Natural Steps four systems condition framework is similar to Daly's model in having society embedded in a biosphere where resources are delivered to society and wastes from society are assimilated (Figure 1). Similar to Daly's model the biodiversity is not necessarily used up but widening the basis of the input and output quality.

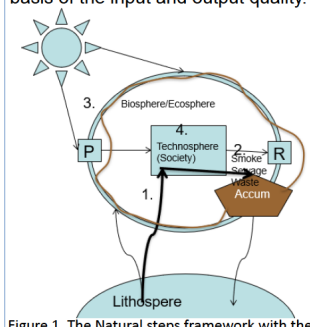

Figure 1. The Natural steps framework with the four systems conditions (also called socio-ecological principles) depicted as number 1-4.

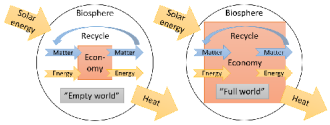

Figure 2. Daly's full and empty world model.

2.3 Source, sink, integrity sustainability

Both the Herman Daly model and the The Natural Step model highlights the feature of not overusing either the resources nor the assimilative capacity on the input and output side of the system. Even though not commonly used, the terms source and sink sustainability seem relevant to use in this context, indicating a long-term, sustainable, use of resources and assimilative capacity.

However, as pointed out biodiversity may be distinguished from this source and sink sustainability, since the diversity is more of a system property that is not used up in the process from input to output and recycling. In systems science this feature is sometimes called the integrity of the system (Richmond 2001, Meadows 2008) suggesting a third sustainability term called systems sustainability. Since this is a very general term, a more unique term can be used instead: integrity sustainability.

In the Natural Step model condition 2 represents the sink sustainability, and condition 3 represents the source sustainability. Both of them can, however, also be said to have an integrity sustainability aspect, where enough capacity must be maintained on both sides.

2.4 GRI (Global Reporting Initiative)

GRI is a widespread voluntary reporting framework for sustainability work by companies and organisations. The environmental part of GRI (the 300-series) consists of the basic approach of energy and mass balances (301, 302, 303), and then the three typical sorts of waste: solid (306), sewage and gaseous waste (305). Biodiversity (304) differs substantially from the other categories by not being quantitative or use performance indicators in a similar way. Again, the label integrity sustainability fits better to biodiversity, while source and sink sustainability fits to the others.

2.5 Two systems ecology textbooks

The H.T. Odum textbooks does not mention the term biodiversity. A possible reason for this may be that the term biodiversity did not have a major breakthrough until 1986 at the famous conference hosted by Edward O. Wilsson and others (see Worster, 1994). Odum's first edition was published in 1983, and is mainly adjusted regarding the energy hierarchy concept in the 1994 second edition. It is, though apparent that Odum is well aware of the aspect, since the term diversity have several entrances in the book index, and are important parts of several models in the book.

Jørgensen (2012) devotes a full chapter to diversity in ecosystems (chaper 10). Noticing that biodiversity is often defined by the three levels mentioned at the beginning (genes, species, landscape), Jørgensen takes a more detailed grip on the concept of diversity. Noting earlier in the textbook that ecosystems have a hierarchical organization, he discuss and calculate the theoretically possible diversity for each one of the hierarchical levels from molecules, genes, cell types, organs, individuals, species, populations, communities, ecological networks, and finally the ecosystem level. For each one of these levels, he gives calculation examples showing that the possibilities for diversity - the number of possible combinations - is overwhelming, often of the theoretical size 10^200 and similar.

A major difference between Odum's and Jørgensen's textbook's are that Odum takes the human presence for granted in his approach. The last part of the book (part four) is named "Systems of nature and humanity", and alongside with natural ecosystems are presented also economic systems of nations (chapter 23), ecosystems with humans (chapter 24), cities and regions (chapter 25), and world patterns (chapter 26). A summary chapter (27) concludes the unity of systems whether human dominated or natural.

Jørgensen on the other hand, don't explicitly omit humans from the systems, but have no examples where humans are parts of the systems other than disturbing it with eutrophication and toxic substances – the traditional environmental impact approach. One way of capturing this is using the categorization by Jablonka and Lamb (2005, 2014) to different types of information carriers where Jørgensen has a main focus of the the two first levels, genetic and epigenetic, while Odum includes also the third level of behavioral evolution.

3. Conclusions

The paper concludes that biodiversity stands out compared to other environmental issues when viewed from the first three angles chosen. While source and sink sustainability are good labels for most environmental issues, integrity sustainability may be a better label for the biodiversity type. The two textbooks also underline biodiversity as a systems property, where integrity sustainability may be a better term. Jørgensen explicitly points out several more hierarchical levels of diversity than the three levels usually pointed out by the biodiversity concept. Finally, the paper also speculates if economic, social, and cultural sustainability can be better captured with the integrity sustainability label.

Circularity: Just Science Fiction? A science fiction prototype experience

Santiago Perez[1], Heather Rogers[2], Malgorzata Lekan[2], Aodhan Newsholme[3]

[1]Université de Technologie de Troyes, Troyes, France. [2]University of Hull, Hull, United Kingdom. [3]University of Hull, Hull, France

Abstract

Since 2015, with the adoption of the Circular Economy Action Plan by the European Commission, the Circular Economy (CE) paradigm was established as a solution to transition to more sustainable societies. The concept of CE, even when it carries many definitions across stakeholders, is widely used among academics and practitioners working towards social, environmental, and economic sustainability.

This article is the result of a workshop during the 2021 Actionable Science for Urban Sustainability conference, where the authors proposed a Science Fiction Prototyping (SFP) session. Such a session established a fictional scenario in the year 2100, where a high degree of circularity has been achieved, from where the participants generated stories about how people might navigate their lives in this circular whole new world. The result is a collection of twelve rich and unique stories describing thought-provoking potential scenarios using vibrant, colourful language for expressing complex ideas and emotions. These stories were shared and discussed to unpack the differences and the themes in common. Each story has undergone a qualitative analysis using the categories of analysis of Governance, Education and learning, Collaboration, Employment, Relationship to objects, and Wellbeing. Those categories were selected by the authors beforehand, based on previous research.

The SFP methodology allowed the participants, not only to forecast a circular future but also to trace back the steps the current society had to have gone through to achieve such a high level of circularity. Reflections on the social, technological, environmental, and economic spheres for each one of the described categories were expressed in the stories. Exploring the operationalisation of the concept of CE, as we understand it today, in a distant utopian and/or dystopian future, resulted in an enriching and telling experience. One exploring the possible advantages and disadvantages of establishing CE as a strategy responding to today's unsustainability paradigm. SFP helped both academics and practitioners to build future scenarios and inquire into the challenges we can potentially face when building more just sustainable societies.

This article relates closely to the SDG 11 and SDG 16. As the article related to the construction of a fictional reality of a circular society, the research is related to the following targets: 11.3, 11,.4, 11.6, 16.6, 16.7, 16a and 16b. All those targets address the conditions that must be fulfilled to generate societies with more sustainable behaviours. The role of institutions and the citizens is tightly entrenched in the resulting stories from the SFP session.

Also, SDGs 12 and 17 are touched by the theme of this article. Methodologies as Science Fiction Prototyping (SFP) in the context of sustainability put in evidence not only the preconceptions and biases from the participants but also the foreseen challenges and obstacles they fear (or fear not) to face. This methodology brings together the scientific knowledge and the intrinsic and extrinsic values of the participants and merge them into a coherent narrative of the future. Such complex narratives are fully charged of the experience of being human, expressed by cultural norms, art, and political expressions.

How do the Ratings that Measure the Sustainability of Universities Integrate the Circular Economy?

Tania Bishara, Joan Manuel F. Mendoza, Daniel Justel

Mondragon Unibertsitatea, Faculty of Engineering, Mechanics and Industrial Production, Mondragon, Gipuzkoa, Spain

Abstract

Circular economy is a concept that is gaining attention as an approach to help accelerate the transition towards sustainability globally, in this sense different types of organizations are adopting aspects of circularity, one of these are Higher Education Institutions through their through its operations and processes with workers and students. In this way, the ratings that measure the sustainability of Higher Education Institutions have emerged, which are intended to provide a framework for understanding sustainability in all sectors of higher education, enable meaningful comparisons over time and across institutions using a common set of measurements, create incentives for continual improvement toward sustainability, Facilitate information sharing about higher education sustainability practices and performance, and build stronger and more diverse communities of students and workers for campus sustainability. Through the participation of institutions in these ratings, they can earn points to obtain a rating that represents significant leadership in sustainability.

This article is focused on analyzing the ratings that measure the sustainability in Institutions of Higher Education (STARS, Times Higher Education, UI Green Metric) in terms of Circular Economy, for this the sustainability ratings of Institutions of Higher Education are compared with the "Circulytics "circularity indicators that measures circularity performance, supports decision making, highlights strengths and blindspot, provides transparency, opens up opportunities in order to identify the level of integration of the circular economy in these sustainability ratings.

As a result of the analysis, it is observed that although the ratings consider aspects such as climate change, energy consumption, material purchases, transportation, waste management, and water consumption, they do not consider a holistic vision of the circular economy, so it is It is necessary that its measurement aspects integrate eco-design criteria, reduction of materials, reduction of materials and recovery of waste through of collection, maitenance, reuse, redistribute, refurbish, remanufacture, recycle, regenerate, share, optimise, loop, virtualise, exchange, servitization, among others.

LCA of Eco-efficient Techniques and Lifestyle: Case-study of a family unit with an agricultural holding

Francisco Mariano[1], António Galvão[2], Dr. João Joanaz de Melo[2]

[1]NOVA University Lisbon, Almada, Portugal. [2]CENSE, NOVA University Lisbon, Almada, Portugal

Abstract

Our society is based on an increasingly global economy and dependent upon many products from the international market. All nations import several products extracted and transformed elsewhere (fossil fuels, food, technological products, and consumer goods, among others). The production and transportation of such products entails high environmental burdens.

Our choices are not only the driver but also the solution to solving our current ecological and climatic crisis. It is essential that we rethink the way we live and consume, avoiding unnecessary consumption, favoring local production, increasing resource use efficiency, and thus building a true circular economy.

The goal of this work is to analyze how a family's environmental footprint can be reduced, through the adoption of a lifestyle that actively seeks sustainable solutions. The environmental performance for a set of these consumption solutions was assessed with life cycle analysis using the EcoBlok method's key performance indicators. The results where then compared to a previous study on Portuguese families' environmental performance that used the same methodology.

The selected case study was an agricultural holding with a family residence, located in the municipality of Castelo Branco in Portugal. The consumption solutions studied were: a rainwater catchment system; a domestic composting installation; food production in a family farming system; and the improvement of the house energy balance through thermal insulation and the modernization of the climatization and sanitary water heating systems. Transportation was not included in the study scope.

The results obtained show that the environmental footprint of a family can be considerably reduced through the application of the proposed solutions. The bulk adoption of the more sustainable solutions studied allowed: a reduction of greenhouse gas emissions by 93% and other air pollutants by 80%, due mainly to the improvement in energy efficiency; a reduction in water abstraction by 84% and of water and of soil pollution by 97%, mainly due to home farming techniques and composting; and a reduction of the need for land use by 95% and of resource extraction by 92%, due to a combination of energy efficiency, home farming and composting.

1. Abstract

The transport industry is a significant contributor to emissions and other toxic wastes which pollute the environment. To alleviate these negative effects, United Nations introduced the Sustainability Development Goals (SDGs). And the automotive industry is constantly striving to improve the Vehicle Development Processes (VDPs) to comply with the SDGs. However, the impact of these improvements in VDPs on SDGs is not investigated thoroughly. Therefore, this paper is a comprehensive attempt to understand and analyse the impacts of improving the VDPs on SDGs. The effect on each goal and target is investigated by questioning its impact on SDGs due to the presence and absence of these improvements in VDPs. Based on the analysis at the goal level, the impacts on SDGs are initially classified into five categories: Indirect Negative Impact, Direct Negative Impact, No Impact, Indirect Positive Impact, and Direct Positive Impact. Further, the impact on SDGs at a target level is analysed, and the results indicated that 55% of the targets had no impact, 36% of the targets had a positive impact, 2% of the targets had a negative impact, and 7% of the targets had both positive and negative impact. To understand this imbalance of impact and to gain further clarification, the SDGs are divided into three groups, namely society (1,2,3,4,5,6,7,11, and 16), economy (8,9,10,12, and 17), and environment (13,14, and 15). The analysis of targets and SDGs in groups indicated that the environmental targets have the most positive impact, followed by economic targets. The societal targets have the least impact among the three. The rationale behind this disparity at the target and goal level was that the automotive industry has been more focused on the economic benefits, and the sustainability factor has been integrated into its processes only recently. Moreover, the concept of sustainability has always been associated with and presumed to be revolving around the environmental aspects. The integration of social aspects such as quality education, gender equality, poverty, and hunger was given little relevance. To alleviate this disproportion, the automotive industry has taken initiatives that indulge in Corporate Social Responsibility. It is being realised that achieving societal SDGs could be vital in developing a better workforce and subsequently lead to sustainable economic growth and thus the economic SDGs.

Although the analysis focuses on all SDGs, the SDGs related to the environment (13,14, and 15) and economy (8,9,10,12, and 17) are more relevant as they have higher direct impacts due to the improvements in VDPs compared to the societal SDGs (1,2,3,4,5,6,7,11, and 16).

Keywords: Impact, assessment, Vehicle-development, synergies.

1. Introduction

The global mean temperature has increased by 0.7°C in the last decade (2009 - 2018) (Sippel, Meinshausen, Fischer, Székely, & Knutti, 2020). Pollution rates and greenhouse gas emissions are increasing, and the high-elevation glaciers are melting (Thompson, 2010). These are all direct consequences and indicators of the ongoing large-scale, pervasive, rapid climate change. To subdue this rapid change in Earth's climate and its impact on the social, economic, and environmental aspects, the Sustainable Development Goals (SDGs) were established by the United Nations General Assembly in 2015 as a part of Agenda 2030. The 17 sustainable goals are displayed in Figure 1. The predecessor to SDGs, the Millennium Development Goals (MDGs), primarily focuses on improving the social aspects of developing countries. However, the SDGs encompass issues across various fields covering social, infrastructural, technological, economic, environmental, and industrial aspects for both emerging and developed countries.

Figure 1: 17 Sustainable Development Goals established by the United Nations

With the introduction of SDGs and the Paris Agreement in 2016, various rules, regulations, and policies governing different industries have been revised with stricter restrictions to accommodate these goals. Many industries were impacted due to these changes in regulations; among them is the transport industry. It is one of the highest contributors to greenhouse gases, accounting for 24% of all greenhouse gas emissions in the EU (Omahne, Knez, & Obrecht, 2021). The vehicle industry has initiated developing efficient and sustainable solutions to keep up with this increasing austerity in regulations. Research is continuously conducted to constantly improve the various processes involved in developing the vehicles, enabling the transition towards sustainability in every aspect of vehicle development. This transition towards 'sustainable solutions' entails changes across different dimensions such as

technological, material, organisational, institutional, and sometimes even political, economic, and socio-cultural (Omahne et al., 2021). These changes across different dimensions could act as both enablers and inhibitors for achieving the SDGs. Thus, in this paper, the manner in which the vehicle development processes (VDP) impact the achievement of the Sustainable Development Goals is analysed.

2. Method

To analyse the impact of improving the VDPs on SDGs, a few elements of the method described in (Laurent et al., 2020) are taken as inspiration and adapted for the method developed in this paper. The method to analyse the impact of VDPs on SDGs includes six significant steps:

1. Identify the research area
2. Define the scope of assessment
3. Identify different processes and activities involved
4. Create two worlds: Baseline and New System
5. Analyse the impact of the new system on SDGs at the goal level
6. Analyse the impact of the new system on SDGs at the target level

2.1. *Step 1: Identify the research area*

The area of research in which the impact assessment is performed is identified. The research area can be narrow or broad depending on the research area determined. In this paper, the wider research area of 'Vehicle Engineering' is considered the focus of assessment.

2.2. *Step2: Define the scope of assessment*

Once the research area is identified, the scope of the research area must be defined. Since Vehicle Engineering is a broad field of engineering and can include many fields, the scope is limited to certain aspects of vehicle engineering. In this paper, the scope is limited to processes involved in the development of the vehicle, i.e., all and any activities and processes required for the development and manufacturing of a vehicle are considered. The scope shall also include the sub-processes required for the preparation and successful implementation of the VDPs.

2.3. Step 3: Identify different processes and activities involved

Different processes and activities involved in developing and manufacturing a vehicle are identified. These include raw material procurement, concept development, model and prototype development, simulation of vehicle models, manufacturing of components, assembly of vehicles, painting of vehicles, testing of vehicles, and end-of-life management of vehicles. Improvements in the vehicle's use phase are not considered for the assessment as these do not fall under the VDPs.

2.4. Step 4: Create two worlds: Baseline and New System

After different processes in the defined scope are identified, two worlds are created: baseline and new system. The baseline is a scenario in which the research in focus is not present or not introduced to the world. Consequences of such a "business-as-usual" scenario on different processes are identified. The second scenario is the new system. In this scenario, the research in focus is introduced to the world. Various positive and negative consequences due to the introduction of this research are identified. The consequences of shifting from a baseline to a new system could be numerous. Therefore, this paper identifies and focuses on the consequences relevant to the SDGs.

For instance, the manufacturing of chassis, components, the assembly of vehicles, and the painting of vehicles consume large amounts of energy and water and are responsible for a large percentage of emissions (Giampieri, Ling-Chin, Taylor, Smallbone, & Roskilly, 2019; Semmens, Bras, & Guldberg, 2014a). If this continues, it will lead to an undesirable consequence of a significant increase in emissions. Thus, improving these processes could curb emissions to a manageable level.

Another example would be in the case of processes such as concept development, prototype development, and simulation of the developed vehicle models. These occur in most cases before the actual manufacturing of the vehicle. Therefore, these processes are essential in shaping the vehicle in terms of energy efficiency, material requirements, and environmental impact. If no improvement is introduced to these processes, the ability to improve material, water, and energy efficiency during the manufacturing phase would be limited. Therefore, improving these processes would improve manufacturing and vehicle efficiency. Furthermore, developing accurate prototype models and simulations of the vehicle would minimise the iterations required in full vehicle testing and crash testing. This is beneficial since the full vehicle testing and crash testing account for a large amount of wastage, energy consumption, and emissions.

2.5. Step 5: Analyse the impact of the new system on SDGs at the goal level

Once the consequences of both worlds (i.e., the business-as-usual scenario and the scenario in which the research in focus is implemented) are determined, the manner in which these consequences impact the achievement of the SDGs is analysed. To analyse the impact of these consequences, the impacts are classified into five levels: Indirect Negative Impact, Direct Negative Impact, No Impact, Indirect Positive Impact, and Direct Positive Impact. To classify a consequence into an impact category, the following questions are asked: Does the consequence of maintaining the practices and processes in baseline impact the achievement of SDGs in any way? And does the consequence of implementing the new system impact the achievement of SDGs?

These questions will clarify the consequences due to the presence and absence of the new system. For example, suppose a process/activity in the baseline scenario proved to act as an inhibitor to SDGs. In that case, it indicates that introducing the new system would serve as an enabler for SDG achievement. Thus, the baseline scenario simply acts to understand and justify the classification of the impact of the new system.

If the impact new system directly enables or contradicts SDG achievement, then it is classified as direct positive impact and direct negative impact, respectively. Suppose the new system's impact leads to a consequence that directly affects the achievement of SDGs positively or negatively. In that case, it is classified as indirect positive impact or indirect negative impact. Weak links such as "the money allocated for the improvement of VDPs can be rerouted to mitigating poverty and hunger" are not considered as they can be stated for any such problem. If such a weak link exists, it is classified as having no impact. Also, if the implementation of the new system has no impact on the achievement of the SDGs, it is classified as having no impact.

With the explained method, each SDG is evaluated, and the obtained results are described in the Analysis section of this paper.

2.6. *Step 6: Analyse the impact of the new system on SDGs at the target level*

Once an initial assessment on the goal level is made, a similar procedure is used to evaluate the SDGs at the target level. The questions previously stated would be asked again for every target of every SDG and classify the impact as stated before (Indirect Negative Impact, Direct Negative Impact, No Impact, Indirect Positive Impact, Direct Positive Impact). Two elements are required to classify the impact as direct or indirect positive and direct or indirect negative. First is a reference to the existence of a problem due to the baseline processes. This shall indicate that due to the current practices, a problem exists and needs to be addressed for achieving SDGs. The second is a reference stating that shifting to the new system could be beneficial. This means that by overcoming the shortcomings presented in the baseline, there are positive or negative effects that impact SDG achievement. These references must be in the form of a research paper, certified reports of established organisations, or verified articles from established organisations. If the consequence of the new system has both positive and negative effects, the target is considered to have both positive and negative direct/indirect effects.

With the explained method, each target of every SDG is evaluated, and the obtained results are described in the Analysis section of this paper.

3. Results

The results from the analysis of the impact of improving the VDPs on SDGs at goal and target levels are presented in this section.

3.1. Assessment of impact on SDGs at the goal level

An initial assessment of the impact of improving the VDPs on achieving the SDGs is performed with the help of the SDG Impact assessment tool. As mentioned in the method section, each goal is categorised into Indirect Negative Impact, Direct Negative Impact, No Impact, Indirect Positive Impact, and Direct Positive Impact. Each goal is questioned on its impact on achieving the SDGs due to the presence and the absence of the baseline and new system and its consequences. Depending on the answer, they are classified accordingly. Obtained results are presented in Figure 2.

Figure 2: Results of assessment on the impact on SDGs at the goal level

3.1.1. *Direct positive impact*

From an initial assessment, the SDGs Clean Water and Sanitation (SDG 6), Affordable and Clean Energy (SDG 7), Industry, Innovation, and Infrastructure (SDG 9), Responsible Consumption and Production (SDG 12), and Life below water (SDG 14) have a direct positive impact on improving the vehicle development processes. Development, manufacturing and production of vehicles are energy and water intense processes, and they contribute to a large percentage of CO2 and greenhouse gas emissions during these phases (Babel, Oo, Shinde, Kamalamma, & Haarstrick, 2020; Fysikopoulos, Anagnostakis, Salonitis, & Chryssolouris, 2012). This might be because many of the VDPs focus more on maximising economic productivity than the sustainability aspect of the process. However, this is changing as more and more companies are trying to adopt more sustainable practices in their VDPs (Alayón, Säfsten, & Johansson, 2017; Enderle, Nowak, & Kvas, 2012; Pechancová, 2017). Improving the VDPs sustainably will help reduce the water and energy consumption, shift to sustainable energy sources, reduce the emissions from the processes involved, and improve material efficiency, thus being directly responsible for achieving the goals mentioned above.

3.1.2. *Indirect positive impact*

From an initial assessment, the SDGs Good health and well-being (SDG 3), Quality Education (SDG 4), Decent Work and Economic Growth (SDG 8), Sustainable cities and communities (SDG 11), Climate Action (SDG 13), and Life on land (SDG 15) have an indirect positive impact due to the improvement in VDPs. One of the primary motivations for improving the VDPs is to enhance the safety of the vehicles and thus the safety of the passengers. Nearly 1 million people every year lose their lives, and up to 50 million people are injured due to accidents. Thus, the automotive industry is constantly striving to improve the safety of vehicles by integrating safety and sustainability in all the processes involved in developing a vehicle (Godoi, Prakash, & Bhandari, 2021). Thus, enabling the achievement of SDG 3.

Improving the VDPs could lead to the automation of many of the processes involved. This would drive the need for more high-skilled labour proficient in (Science, Technology, Engineering, and Mathematics) STEM fields. This forces the education system to train the students with skills required for the industry (Griffin & Mary, 2020). Thus, improving VDPs will help achieve a more quality education (SDG 4). This requirement for high-skilled labour would further mean that majority of the employees enjoy higher compensations and a better working environment. Thus, helping achieve decent work and economic growth (SDG 8). As previously mentioned, the processes involved in vehicle development produce a large share of wastes in the form of emissions, and toxic sludge, thus polluting the air, water, and land. In the recent times, more focus has been given to curbing these emissions and therefore, it would help in reducing health-related issues due to pollution, reducing the water consumption, thus conserving the marine and terrestrial ecosystems, and thus enabling the achievement of developing sustainable cities and communities (SDG 11), combating climate change (SDG 13), and protecting the life on land (SDG 14 and SDG 15).

3.1.3. *Indirect negative impact*

From an initial assessment, the SDGs No poverty (SDG 1), Zero Hunger (SDG 2), Gender Equality (SDG 5), Reduced inequalities (SDG 10) have an indirect negative impact due to the improvement in VDPs. Improving the VDPs would entail automation of processes, which would further cause the replacement of low-skilled jobs (Griffin & Mary, 2020; Khatiwada, 2020) with high-skilled labour. Since a considerable share of employees working in the automotive industry are low-skilled blue-collar jobs, replacing these jobs would tip the opportunities toward high-skill labour. Inequality within the economic classes is further increased. Thus, the aim of alleviating poverty and reducing hunger is led in a negative direction. Therefore, the achievement of SDGs No poverty (SDG 1), Zero Hunger (SDG 2), and Reduced Inequalities (SDG 10) are negatively impacted due to the improvement in VDPs. The number of female employees in the automotive industry is low.

Furthermore, the number of women with STEM education is comparatively lower. Therefore, this requirement for high-skilled workers would further aggravate the imbalance of unequal participation with respect to gender (Griffin & Mary, 2020; ILO, 2019). Thus, the achievement of gender equality (SDG 5) is negatively impacted.

3.2. Assessment of impact on SDGs at the target level

After an initial assessment at the goal level, the impact of improving VDPs on SDGs is re-evaluated at a target level. Every target of every SDG is questioned on its impact in achieving the SDGs in the presence and absence of the new system. Depending on the answer, they are classified accordingly. Unlike at the goal level, a target can be classified as having both negative and positive impacts. Although the number of goals classified as 'No Impact' in the previous section is minimal, it is found that 55% of the targets have no impact due to the improvement in VDPs, as displayed in Figure 3.

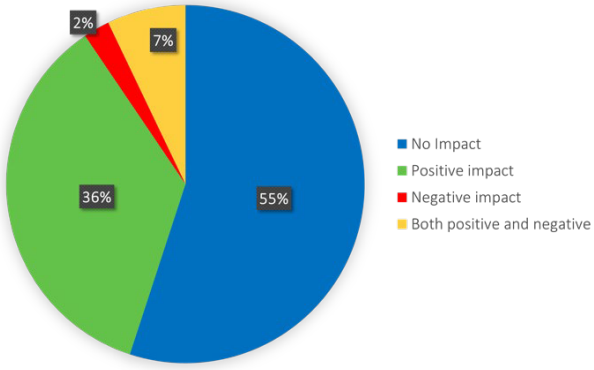

Figure 3: Results of assessment on the impact on SDGs at the target level

To investigate and understand this division of impact on SDGs at the target level, the SDGs are classified into three groups: Society, economy, and environment, as mentioned in (Vinuesa et al., 2020). The goals in each group are displayed in Figure 4. In each group, the assessment is performed at a target level to understand which aspect of SDGs has the highest impact and lowest impact due to the improvement in VDPs.

Figure 4: Classification of SDGs

3.2.1. *SDG Group: Society*

The impact of improving the VDPs on achieving the SDGs pertained to societal aspects is evaluated, and the results are presented in Figure 5. The percentage share of the targets is depicted in Figure 6.

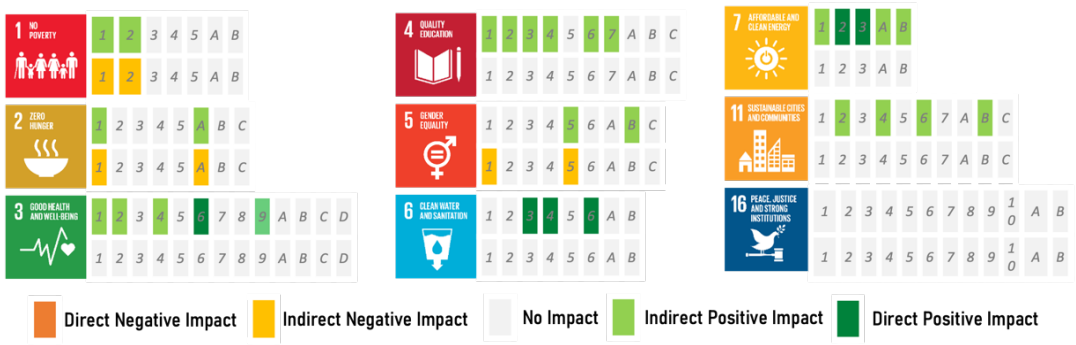

Figure 5: Impact Assessment of the societal group SDGs at the target level

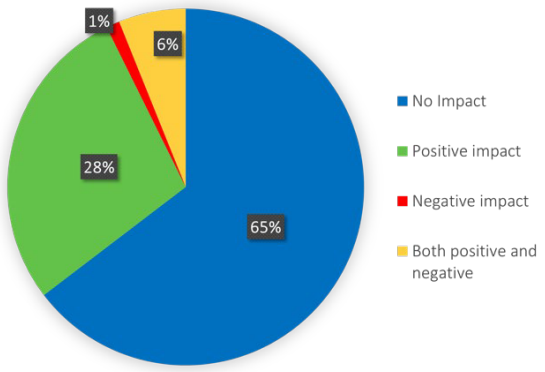

Figure 6: Percentage share of the Societal group SDG targets

The traditional methods of VDPs involved a significant amount of manual work. This provided a significant percentage of employment for low-skilled and blue-collar employees. However, in recent times, to improve efficiency, introduce sustainability, and reduce the cost of developing vehicles, much of this low-skilled work is being replaced by automation, putting the low-skilled and blue-collar jobs at risk (Khatiwada, 2020). Moreover, with the shift from combustion engine-based vehicles to electric motor based vehicles, the number of components required for the vehicle is decreased, further causing a loss in many jobs (Frey & Osborne, 2017; Griffin & Mary, 2020). Since the automotive sector is a major employer of the low-skilled workers, this shift towards automation and electric vehicles is acting as an inhibitor for achieving the SDG goals 'No poverty' and 'Zero hunger'. However, several reports and articles state that this improvement in VDP does not affect a large share of employment. Furthermore, it will create even more opportunities in other parts of the automotive field, such as in the electricity generation, manufacturing of batteries, electrical components and machinery, building required infrastructure and maintenance of charging stations (UNECE & ILO, 2020), development and

provision of services and products to facilitate the future transport requirements (Griffin & Mary, 2020). Therefore, it also acts as an enabler for achieving the SDGs 'No poverty' and 'Zero hunger'.

Some of the important motivations behind improving VDPs are to curb the emissions, reduce the pollution and the health problems caused due to that, and improve the safety of the vehicles and thus ensure the safety of the passengers. Air pollution is considered one of the major causes of non-communicable diseases (Schraufnagel et al., 2019), health issues in pregnant women (Hu et al., 2014; Malley et al., 2017) and also children (World Health Organization (WHO), 2018) which can even lead to their death. The number of people killed and injured due to vehicular accidents is very high. Close to 1.3 million people are killed, and up to 50 million people are injured. Therefore, an improvement in VDPs reduces air pollution and thus, reduces the number of people affected due to the pollution, alleviating the number of fatal accidents as well. Therefore, it acts as an enabler for achieving SDG 3, 'Good health and well-being'.

A high-skilled and well-trained workforce is necessary to automate processes and improve modelling and simulation methods. Core skills such as social and interpersonal skills, optimal management of tasks, and foundational and technical skills become an absolute requirement to get employed. Interviewers have stated that it is increasingly difficult to identify and recruit engineers with relevant skills (Khatiwada, 2020) due to the lack of quality education that serves and trains the students with the skills required for being industry-ready. Therefore, this immediate skills requirement will encourage the education and vocational training systems to integrate these skills into their curriculum. Thus enabling quality education for all men, women, and youth (Anderson & Rainie, 2017; ILO, 2017). Thus, an improvement in VDPs allows the achievement of SDG 4, Quality Education.

Although there is a growing acknowledgement that women are underutilised in the automotive industry, the number of women employed in the automotive industry is three times less than that of men in EU member states (Griffin & Mary, 2020). They represent only 27% of the workforce (Of & Statistics, 2015), and they make up less than 8% of all executives in automotive companies, half of which had no women executives in their team in 2018 (Findings, Hackett, Kruger, & Muller, 2018). Moreover, a recent survey from ILO and LinkedIn shows that women are less likely than men to possess the required digital skills that are necessary in the automotive industry (ILO, 2019), as the number of women enrolled in STEM-related fields of study are two times less than that of men (Harvey, 2016). If this trend continues, the inequality will further be aggravated. But with the improvement in VDP, the recognition of the requirement to improve gender equality is increasing. Therefore, an improvement in VDP could both hinder and very indirectly enable the progress of achieving SDG 5, Gender Equality.

Vehicle development is water and energy-demanding process. Approximately 5.2 - 5.95 m^3 of water per vehicle is being utilised directly in the manufacturing processes (Bras, Tejada, Yen, Zullo, & Guldberg, 2012; Semmens, Bras, & Guldberg, 2014b) and 41.8 MJ/kg of energy per vehicle is being

utilised (Sato & Nakata, 2020). Such levels of water consumption occur mainly from freshwater sources, and the energy being utilised may not entirely be from renewable sources. Moreover, freshwater ecosystems are polluted by toxic sludge released during painting, water that is discarded from cooling and lubrication processes. However, more recognition is being given to developing practices to recycle the water. Practices such as using closed-loop water systems and recirculating stormwater for cooling are being followed to reduce freshwater consumption (Alayón et al., 2017).

Furthermore, many companies such as Volvo and Scania are improving their VDPs so that their whole manufacturing and production process are carbon-neutral by following practices such as using industrial waste heat and biogas for heating purposes. This shift towards using renewable energy and waste heat energy would encourage policymakers and investors to develop more infrastructure on renewable energy. This could further allow for the provision of renewable energy not only for industries but also for all people.

Therefore, improvements in VDPs act as an enabler towards achieving the SDG 6 Clean water and sanitation and SDG 7 Affordable and Clean Energy.

This shift towards renewable energy would reduce CO2 emissions and reduce the stress on the local ecosystems and protect local natural heritage. It further enables less wastage from the automotive industry. Thus, preserving the locality and making it more sustainable for human settlement. Therefore, improving the VDPs will help achieve SDG 11, Sustainable cities and communities.

3.2.2. *SDG Group: Economy*

The impact of improving the VDPs on achieving the SDGs pertained to economic aspects is evaluated, and the results are presented in Figure 7. The percentage share of the targets is depicted in Figure 8.

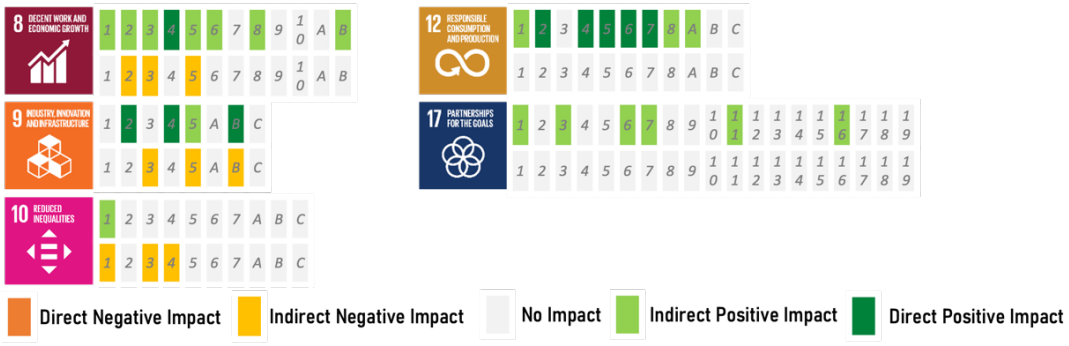

Figure 7: Impact Assessment of the economic group SDGs at the target level

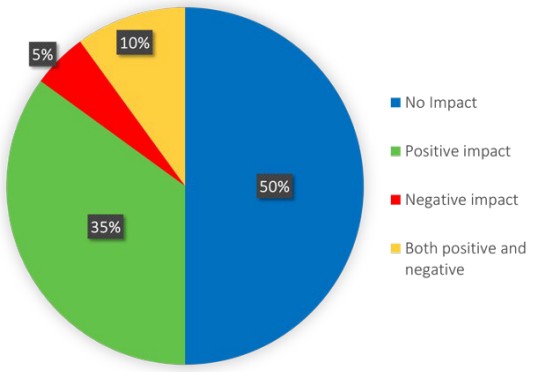

Figure 8: Percentage share of the economic group SDG targets

The impact of improving the VDPs on SDG 8 and SDG 10 is similar to the effects on the societal group. Improving the VDPs in emerging countries such as India, which hosts several manufacturing companies, would drive up the employment rate and reform the education system to meet the employer's requirements (Ma & Zhang, 2019). This improvement also means automating some jobs, transforming, and creating jobs in other forms. This type of job creation depends on sustainable enterprises that foster innovation and generate inclusive growth and productive employment (ILO, 2017). However, in emerging countries, where the share of low-skilled blue-collar employment is relatively higher than the availability of high-skilled workforce, shifting the employment requirement towards high-skilled jobs would cause an imbalance and cause a higher loss in low-skilled jobs (Dachs, 2018), as explained in the societal section.

The benefits and limitations of improving VDPs for SDG 9 and SDG 12 are similar to that of other SDGs. SDG 9 has particular synergy with SDG 8 and SDG 4. SMEs play an essential role in promoting inclusive and sustainable industrialisation and fostering innovation (Small and Medium Enterprises). They are more resilient to the continuous technological changes and improvements in the automotive industry. This type of adaptability and innovation in SMEs allows for more employment with higher quality and compensation. Although they are resilient, they are always trying to catch up with these technological changes and improvements rather than prepare for the future. This is mainly due to the lack of funds. Therefore, SMEs would require proper funding to enable their involvement in macroeconomics and develop an efficient workforce with the required skillset. This would further allow them to compete or collaborate with multinational corporations.

However, many of the R&D sectors are located in developed countries rather than in emerging countries, thus creating more bias in terms of employment standards between emerging and developed countries (Needham, 2014). This means manufacturing will continue to happen in emerging countries where labour is cheap. Even some of those jobs could be automated, leading to further losses concerning economic stability. Thus, improving VDPs could enable the achievement of SDG 8, SDG 9, SDG 10, and SDG 17. But also as an inhibitor in achieving SDG8, SDG 9, and SDG 10.

One of the most beneficial consequences of improving VPDs in terms of economy and sustainability is that consumption is optimised. This optimal use of materials would mean that the natural resources are efficiently utilised, and the wastes and emissions released from these processes are minimised (Hąbek & Lavios Villahoz, 2018). This means the employees are trained about the importance of following sustainable practices and the economic benefits of following such practices. This form of benefits would further influence transnational companies to adopt more sustainable practices (Gaudillat, Antonopoulos, Dri, Canfora, & Traverso, 2017) and integrate them into the national policies (da Rocha, 2017). Therefore, improving VDPs will act as an enabler for achieving SDG 12.

3.2.3. *SDG Group: Environment*

The impact of improving the VDPs on achieving the SDGs pertained to environmental aspects is evaluated, and the results are presented in Figure 9. The percentage share of the targets is depicted in Figure 10.

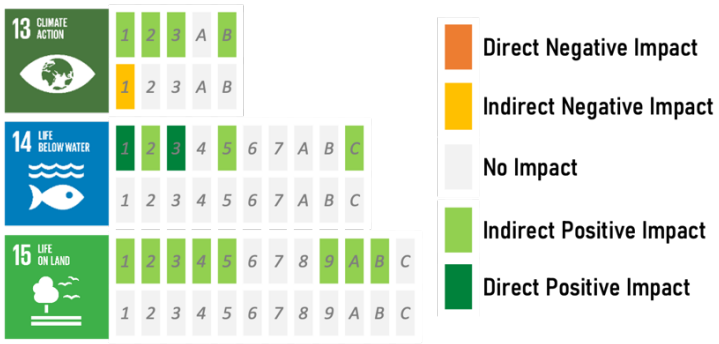

Figure 9: Impact Assessment of the environmental group SDGs at the target level

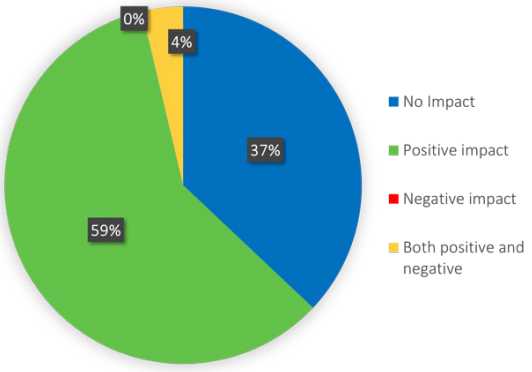

Figure 10: Percentage share of the environmental group SDG targets

One of the important consequences of improving the VDPs and the reverberation of achieving other SDGs is to protect and conserve the natural resources and thus alleviate this rapid climate change. The national policies, regulations, and standards are being reformulated to achieve the climate goals. This reformulation and the need to get ahead of the sustainable economic growth led to companies integrating many sustainable practices such as improving water efficiency (Schlei-Peters et al., 2015), energy efficiency, and reducing the automotive wastes (Zini, Longhi, Jonko, & Giovanela, 2020). This

helps reduce pollution by minimising the toxic sludge released into the marine ecosystems and reducing oceanic acidification. Furthermore, the policies are reformulated such that for a share of the land a company uses for its uses, it must plant trees for a percentage of the land it uses. Also, companies have started practices to preserve biodiversity as they are affected indirectly by the emission caused by VDPs (Jasiński, Meredith, & Kirwan, 2016). Many companies even invest in Corporate Social Responsibility practices and try to conserve the local biodiversity. Barren lands are sometimes used so that the fertile land is not torn down to make way for the companies. These practices help achieve SDG 13, SDG 14, and SDG 15.

3.3. Synergy and trade-off interaction between SDGs

While assessing the impact of improving VDPs over SDGs at both goal and target levels, it was observed that there are several synergies and some trade-offs in achieving them, i.e., achieving one goal could help achieve another goal or even act as a hindrance. The different synergies and trade-offs identified within the context of the vehicle development process are displayed in Figure 11.

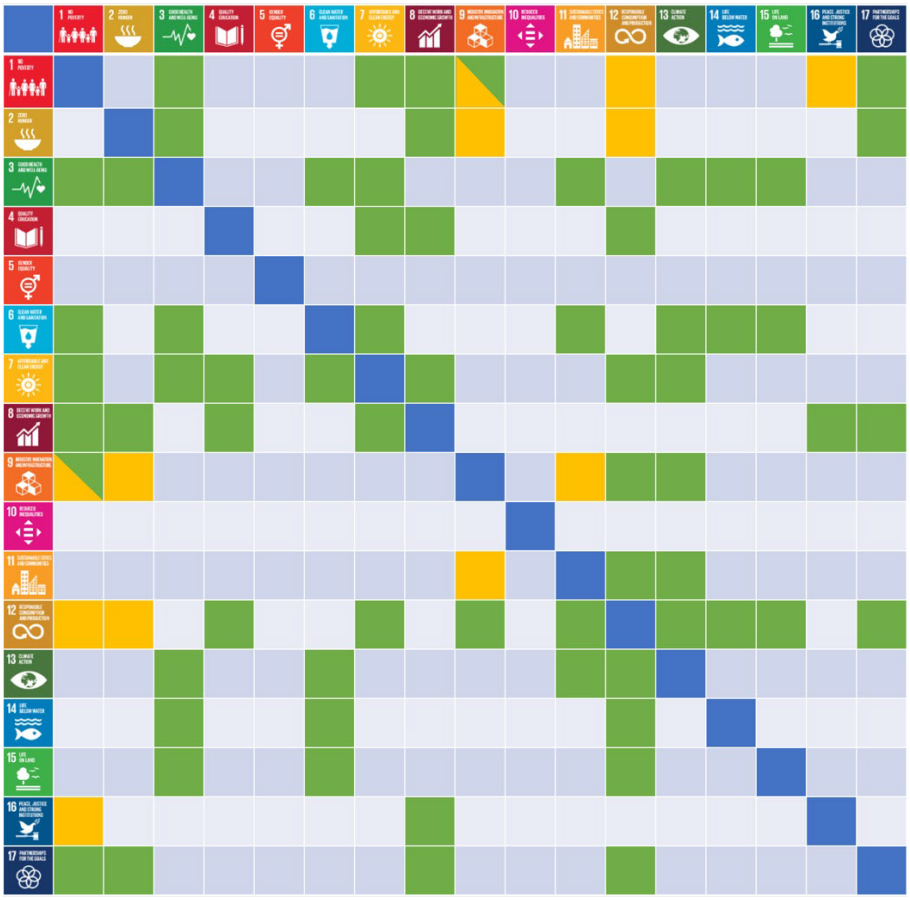

Figure 11: Synergy and trade-off interaction effects between SDGs

4. Conclusion

This paper focused on understanding the impacts of improving the vehicle development process on Sustainable Development Goals by developing a comprehensive method to analyse the effect at both goal and target levels. The impact is divided into five categories. The category in which a particular goal is classified depends on the answers to the questions about the impact of the presence and absence of the improvement practices. From an initial assessment, the different impacts on SDGs due to the improvement in VDPs were determined, and the reasons behind it were briefly introduced. Subsequently, the assessment of impact due to the improvement in VPDs on SDGs at the target level indicated that 55% of the targets had no impact, 36% of the targets had a positive impact, 2% of the targets had a negative impact, and 7% of the targets had both positive and negative impact. This disparity is analysed further by dividing the SDGs into three groups: society, economy, and environment. The impact on each target was assessed. It was found that the targets and goals related to the environment had the highest positive impact on improving the VDPs, followed by the economy group. The targets and goals from the society group had the least impact.

This disproportion is mainly contributed to the automotive industry's misconception of the idea of 'Sustainability' and its principal focus on economic benefits. Sustainability has always been associated with environmental aspects, and the societal aspects of sustainability were given little relevance. Moreover, being a competitive industry, the economic aspect was more focused. It can be noted that even the positive impacts on targets in the societal group can be credited to the improvement in environmental aspects such as clean water and lesser air pollution. However, with the introduction of SDGs, the societal aspect of sustainability was introduced relatively recently, and many practices such as Corporate Social Responsibility are being introduced to alleviate this disparity as it is being realised that achieving societal SDGs could be vital in developing a better workforce and subsequently lead to sustainable economic growth and thus the economic SDGs.

This paper was an extensive attempt to understand the influence of vehicle development processes on SDGs and vice versa. The method involved identifying literature that confirmed the problem's existence and the possible benefits of introducing solutions to the issues identified. However, most assumptions were subjective, and the analysis was qualitative. More tools, case studies, and models are required to perform a more quantitative analysis of the influence of VDPs on SDGs and the interdependencies between SDGs.

Abstract

Although the corpus of gamification and participatory backcasting, a strategic planning process, keeps growing, more empirical research is needed to fully understand how an entirely gamified backcasting process can be carried out online. This article explores how gamefulness contributes to overcoming some of the challenges of online backcasting, such as keeping the participants engaged while working remotely for different units and pursuing diverse priorities. Analyzing the process to develop the GRI Academy's (the online training platform of the Global Reporting Initiative) strategic roadmap as a fully gamified online activity, some findings indicate that using some of the playful elements online systems use the most, such as badges and a leader board, may play no role for the participants' engagement; however, self-made avatars seem to be a source for relating with the content they create. The 32-hour long planning process took place between February and June 2021; by the time this article was written, most of the prioritized actions for the short-term were already underway. This interpretative study is intended to serve as a steppingstone for gamifying further online backcasting experiences, facilitating the selection of gameful elements, tools, and methods to be implemented throughout the entire strategic planning process.

GAMEBACK was developed as an approach to contribute to SDG 12.8 – facilitating practice shifts towards more sustainable lifestyles, as it explores gamification from the perspective of "technological, economic, cultural, and societal developments in which reality is becoming more gameful". This case elaborates further on the framework's first intention by presenting an evidence of a process that harnesses technological developments towards enhancing capacity building and facilitating transparency building worldwide, which is also in line with three of the five targets of the SDG 17.

Keywords: Online backasting, gamified strategic planning, gamification, participatory processes, COVID-19

1. Introduction

Participatory Backcasting, a strategic planning methodology characterized by its crafting of a common, ideal, sustainable visions and scenarios towards which current actions can be defined, planned, and strategized as roadmaps "looking back from the future" (Quist, 2011), is an approach that has largely been implemented through workshops and in-person setups. Participatory backcasting (PB) involves a wide range of societal players defining and searching for common solutions and conditions to meet shared visions, thus bringing together social, economic, and environmental aspects to facilitate transitions towards sustainability (Quist and Vergragt, 2006). Participatory backcasting (PB) has been recognized as a promising approach to tackling today's wicked sustainability challenges. PB empowers diverse stakeholder groups to collaborate towards the establishment of a direction, aligning their efforts and committing to act; this is, enabling shared leadership (Hull et al., 2018) at global, national, regional, and organizational levels across different industries and sectors (Gonzalez et al., 2020; Sandström et al., 2020; Wen et al., 2017). The participatory processes also require critical thinking and reflective decision-making that may take the participants out of their comfort zone. Thus, finding approaches to enable future social action and sustainability solutions requires experiences with shared meanings, co- owned objectives, and self-determined action plans (Bodinet, 2016). Some of the shortcomings of PB include a limited inclusion of end-users, difficulties in developing detailed roadmaps, dominance from individual participants, biased judgments, establishing trust and confidence both in the process and the results, or even keeping the interest and engagement of the participants, particularly in processes that are either too short or span through several months/years (van de Kerkhof et al., 2002; Quist, 2007; Carlsson-Kanyama et al., 2008; Zimmermann et al., 2012).

Research about the topic notes that participatory backcasting is "an interactive workshop-based method" (Thoren and Vendel, 2018) that encourages involvement, learning, and "breakthrough leaps" for improvement (Gjellebæk et al., 2020). In most of the recent literature where PB features as a fundamental part of a planning process, it is reported as a workshop (or series of); working sessions and focus groups (Cuppen et al., 2020; Everard et al., 2021; Vitale Brovarone et al., 2021), or proposed as meetings where it is possible to interact with participants and give them a sense of agency, for example (Bendor et al., 2021). Depending on their scale and intention, these processes could be multidisciplinary and inter-sectoral; or limited to a small number of members of the same organization or even the same team. Backcasting can also be top-down as the result of expert-based interactions or bottom-up through the consolidation of future images and visioning (Timislina, 2021).

PB's interactive and participatory nature, which includes the provision of feedback, goal setting, and overcoming challenges, presents ample room for the implementation of gameful approaches, a set of activities that denote the qualities of gaming (Deterding et al., 2012). These approaches can incentivize higher motivation levels among participants and potentially invite further engagement beyond the process itself (Guillen Mandujano et al., 2021). Gamification is an umbrella concept that broadly refers

to the intentional application of game-inspired principles into activities, services, or systems, serving instrumental and experiential ends (Liu et al., 2017); thus, motivating behavioral and psychological outcomes with potential to initiate change, both at the individual and communal levels, enabling cognitive, affective, motivational and social benefits (Hamari, 2019). Gamification presents itself as an approach to enable participants' engagement and motivation throughout the entire process, either in-person or online.

While the last couple of years have seen a proliferation of non-academic resources (online tutorials, consultancy toolkits, blogs) for carrying out strategic planning processes online, some incorporating games at some point, none of them presents backcasting as an entirely gamified process. This situation is also reflected in academic research studying PB processes online, which is scarce. On the other hand, the literature on considerations and implications of online collaborative experiences keeps increasing, highlighting technical and physical factors to consider. The former represents a barrier to accessibility in many dimensions, from access to the internet to limitations related to the type of device, operating systems, licensing, updates, etc. Physical challenges range from distractors and non-verbal actions, like keeping the cameras off (Gerhes et al., 2021), to overall levels of stress and resilience, with the term "Zoom fatigue"[1] becoming more relevant in the planning and execution of online activities. Furthermore, with the COVID-19 pandemic, people are experiencing more anxiety, isolation, and even depression, appearing unresponsive when attending online synchronous meetings, affecting the interactions' nonverbal dynamics, and retaining attention as they multitask online (Peper et al., 2021).

Against this background, the designers of online participatory experiences, Participatory Backcasting included, should be able to keep the participants engaged and capable of producing the desired results, bearing in mind the physical and technological limitations inherent to the virtual, collaborative setups. In this paper, we question whether considering the participants of a fully gamified online backcasting process as players of an online gaming experience contributes to overcoming some of the shortcomings of online interactions and even of backcasting in general. Therefore, this study poses the research question of **what experiences and best practices emerge from applying fully gamified participatory backcasting processes online?**

This best practice presentation is structured as follows: Section 2 describes the case analyzed, including the methods and tools applied. Section 3 presents the results that lead to the discussion (section 4), and Section 5 is the conclusion.

2. The Case Study

[1] The term not only applies to the teleconferencing program Zoom but to all forms of videoconferencing.

To address its research question, this interpretative study presents the development and outcomes of a best practice where a gamified backcasting framework, called GAMEBACK, was entirely implemented as an online activity. This section presents the context and methodology applied.

2.1 The case organization

From February to May 2021, the principal researcher facilitated the delivery of a gamified backcasting process together with members of the executive and management teams of the Global Reporting Initiative (GRI). The GRI is a leading organization in sustainability reporting that created an online alternative to its existing in-person training offer, named the GRI Academy. While the GRI Academy was originally developed to complement the GRI's well-known in-person training and certification scheme, the high demand for online training derived from the COVID-19 pandemic led the GRI Academy team to speed up their internal development plan.

The GRI Academy team had two clear objectives: i) develop their long-term strategic roadmap; and ii) identify opportunities for improving their users' experience, particularly their learning journey. With these ends in mind, the gamified online strategic planning process aimed at immersing members of the GRI executive and management teams in a first-hand experience of gameful approaches with the potential of leveraging their programs.

2.2 The methodology

While a Google search of "backcasting online" (November 24, 2020; February 23, 2021) returned nearly half a million entries, most of them related to blogs, definitions, and training kits from consultancies. A search of academic research on the topic, introducing the words "Backcasting" and "online" in the SCOPUS database, returned nine articles in February, June, and September 2021. None of these publications touches upon the possibility of carrying out participatory backcasting as an online activity in its entirety. One of the closest academic publications on the topic, called e-backcasting, applies an iterative process through social media to formulate visions for the city of Abuja, Nigeria (Achuenu, 2021) and offers an interesting insight into the design and application of social media platforms to engage participants across the city. The little academic information about backcasting processes implemented online poses an opportunity to explore different approaches to enable efficient, interactive, and valuable backcasting without having the participants physically together.

Given the researcher's involvement in implementing the gamified backcasting framework (GAMEBACK), the data collection methods used for this case include observation, unstructured interviews, recording of the sessions, and textual analysis. Figure 1 illustrates the steps to build this best practice; the steps are explained in the following subsections.

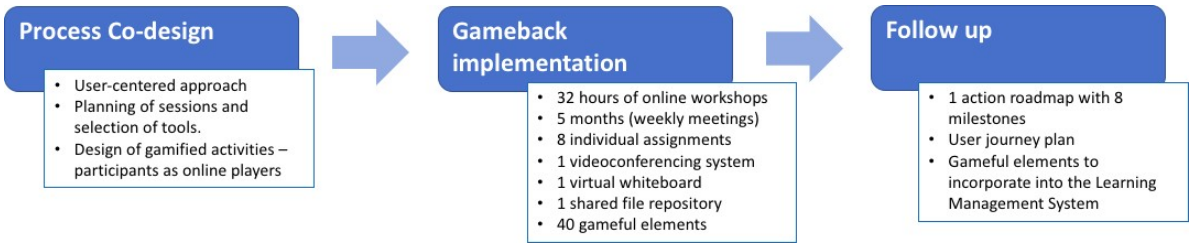

***Figure 1**. Steps to build the best practice*

2.2.1 The implementation framework

The process was developed according to GAMEBACK, a fully gamified backcasting framework developed during 2019-2020. This framework brings together the five steps of the backcasting process (Quist et al., 2011; Quist, 2016) with six elements of game design that facilitate the creation of gamified experiences: information, exposition, choice, reflection, engagement, and play (Nicholson, 2015). Furthermore, this framework aims to help overcome some of the biggest challenges of PB, such as keeping participants motivated to partake throughout the process (particularly in very lengthy ones) and facilitating an experience that invites them to follow up on the planned agenda (Guillen Mandujano, 2021). Considering the GAMEBACK framework was developed through the retrospective analysis of two cases and tested in two different academic setups (Guillen Mandujano et al., 2021), the present research represents its first application as an online process, building upon the postulations that:

1. The process is co-designed with people who will also partake in the experience. This step intends to tailor the activities according to the needs and objectives of the groups involved.
2. The participants are aware that this is a gamified strategic planning process and are invited to consider themselves serious players, meaning they know they will engage in game-like activities that have other purposes than entertaining.

2.2.2 The co-design process

The process was designed following a user-centered design approach, considering limitations such as design time, user feedback collection and application, missing the big picture, and lack of communication and practices to overcome them (Mao et al., 2005; Sy and Miller, 2008). During the preparation stages, the principal researcher held several meetings with the two team members of the GRI Academy responsible for driving the strategic planning process; both persons were also participants in the complete process. These meetings facilitated the optimization of both the design process and the implementation. The latter included two feedback streams: directly after the strategic planning session and a continuous dialogue through the discussion board. This way, the users' feedback was promptly collected and introduced.

To meet the objective of improving the learning journey of the GRI Academy users, the implementation of GAMEBACK followed some of the characteristics of a Massive Online Open Course (MOOC), the format used by the GRI Academy to deliver its programs. Moreover, part of the experience consisted of

participants to walk in the shoes of their users. The experience helped the participants gain a different perspective to include in their strategic actions, facilitating the discovery of elements that they would like to see as part of their programs (or not) and other features that may help improve the overall learning experience.

Expectations setting, time planning, and implementation overview - The online application of GAMEBACK had two approaches: individual, asynchronous work, and live sessions with the group. For the former, the participants could access the material at their own pace and, minding the set deadline, complete tasks according to their time availability and understanding of the content. The content developed through individual activities serves as input for the online group work.

The live interactions allowed for real-time group reflection, exchange of feedback and reaching agreements. The implementation was divided into two phases:

- Phase 1 focused on the roadmap development and had the presence of 2 members of the Executive Team (ET) and 1 member of the Management Team (MT) for all the sessions. Two additional ET members joined a workshop to validate the strategic problem orientation and input to the vision. One additional member of the MT joined two workshops to facilitate the transition to Phase 2.

- Phase 2 aimed at improving the user experience and overall offer of the Academy. Besides the 3 people of Phase 1, three new members joined the discussion, one of them part of the MT.

The resulting Strategic Roadmap and Action Plan was validated by all the members of the Executive Team through an online workshop.

Tools and interactions - The process was designed using a series of tools that comprise many of the most used Learning Management Systems gamification elements, such as progress bars, badges, and discussion boards. Because of the objectives of the process and its bringing together participants from different teams across the organization, the process happened in weekly sessions. This way, the participants could plan their participation according to their daily responsibilities and availability. All sessions were scheduled before the process kicked off, preventing delays due to unavailability or difficulty finding dates that worked for everyone. The process was carried out as follows:

- 32 hours of online workshops in a five-month period (mostly weekly meetings). All these sessions were recorded and used as data to consolidate the current best practice.

- 8 individual assignments (using templates, which included game-like elements previously designed by the facilitator) to provide input for the next session to be discussed as a group. Badges were given for: prompt returning of the assignment, additional input provided (not part of the assignment), finding Easter eggs, and thoroughness of the input.

- additional material to explain the assignments and/or part of the online working sessions, like handouts and future stakeholder profile sheets (personas).

- a video conferencing system (Zoom) that allows virtual whiteboards and show presentations.

- a virtual whiteboard (Mural) to facilitate group work.

- shared file repository to access all the material (SharePoint) that included a Word document to play the role of a discussion board.

Selection and implementation of the gameful elements - The second postulate of GAMEBACK, considering the participants as players, led to analyzing the motivations to play games online as a reference for selecting the activities and game-like elements to be implemented throughout the process. To this end, this case applied Yee's gamer-motivation model (2006), translating the motivation to play as the desire to co-develop a strategic plan online rather than hiring an external party to do the job for them.

The participant selection criteria, this is, the selection of people to invite to partake of the process and become players, consisted of factors such as the participants' time availability, their function within the GRI, their length in the organization, role within the Academy's structure, and decision-making capability. While the process could benefit from the experience and suggestions from all the people behind the courses, during the design process, the player selection criteria determined the size of the group, which ended up being a small one comprising people in top-management positions and responsibilities of the Academy's key processes. When additional input was necessary, selected team members, appointed by the process' participants, would be approached to collect the information.

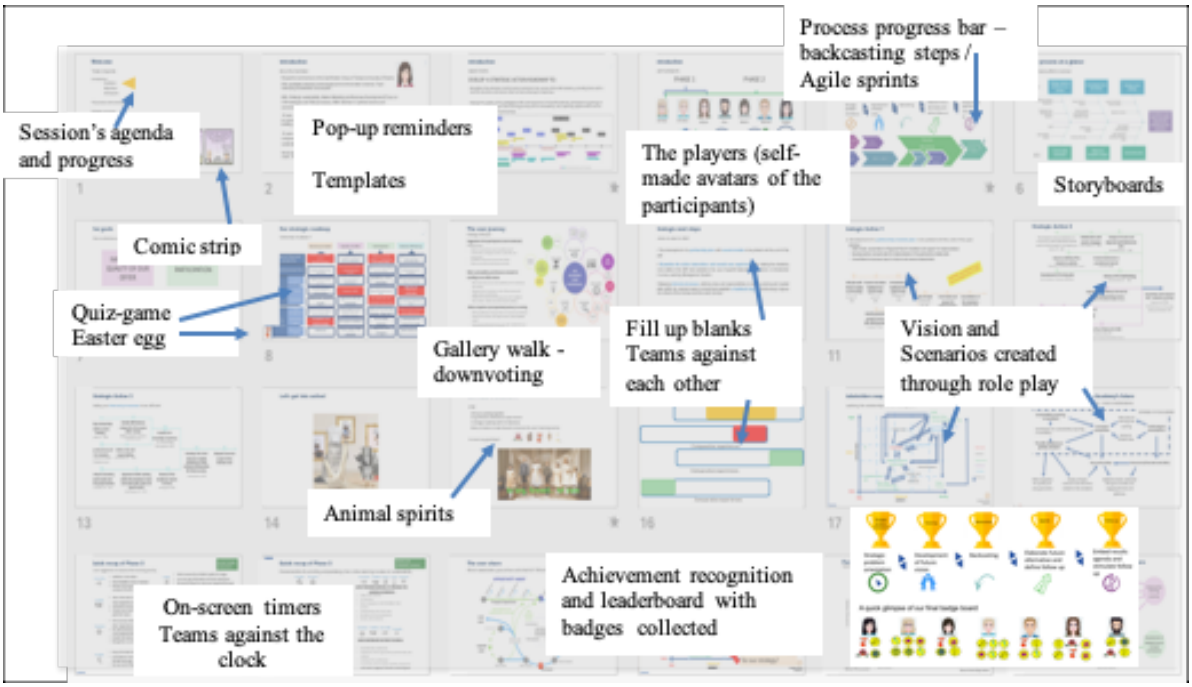

***Figure 2**. Some of the applied gameful elements*

According to Yee's model (2006), there are three overarching components for playing online: achievement, immersion, and social. These components allow identifying the purposes of each element that afford game-like experiences have. Table 1 presents some of these gameful elements, which are also illustrated in Figure 2. The complete list of gameful elements is available in Appendix A.

It is worth noting that the subcomponent "escapism," which implies hiding away from real-life problems in online environments, is here presented as the opportunity for the team to discuss issues that they would not address in their daily activities. Thus, the facilitated online interactions were a sort of a "safe space" from their routine.

Table 1. *Gameful elements according to player motivations..*

	Purpose	**Game-like element**	**Application**
ACHIEVEMENT	Advancement	Agenda progress. Process track (every session)	Check in. Progress bar throughout the entire session
	Mechanics	Templates to provide input individually and as a team. Also to review what the others introduced	Individual input sheets and teamwork during live sessions
	Competition	Two teams against the clock	User journey session
IMMERSION	Discovery	Easter eggs with information or with badge earning opportunities (animal spirit guides)	Two individual input sheets and during four live sessions
	Role-playing	Understanding the Academy's current and future stakeholders	Visioning session
	Customization	Avatar creation and presence on discussion boards	Created before the backcasting step started, the avatars featured throughout the rest of the process.
	Escapism*	Session-specific whiteboards	Every session
SOCIAL	Socializing	Express emotion with mime. Various games.	Check in / check out activities
	Relationship	5-word summaries. Ice-breakers.	Activity reflection and translation of outcomes into elements of the roadmap
	Teamwork	Fill out blanks against a timer Downvoting in a gallery walk	Three sessions (one with the timer on screen)

2.2.3. The backcasting process

Despite being designed for in-person interactions, the GAMEBACK framework offers an opportunity to carry out the strategic planning process in asynchronous, mixed, online interactions that combine online group work with individually developed offline input. During the co-design process, it was

possible to identify the questions that would guide the selection and implementation of game-like experiences. To do so, the GAMEBACK implementation template (Guillen Mandujano, 2021) was used, reviewed, and adjusted throughout the process. Figure 3 shows the final version of the GAMEBACK implementation plan.

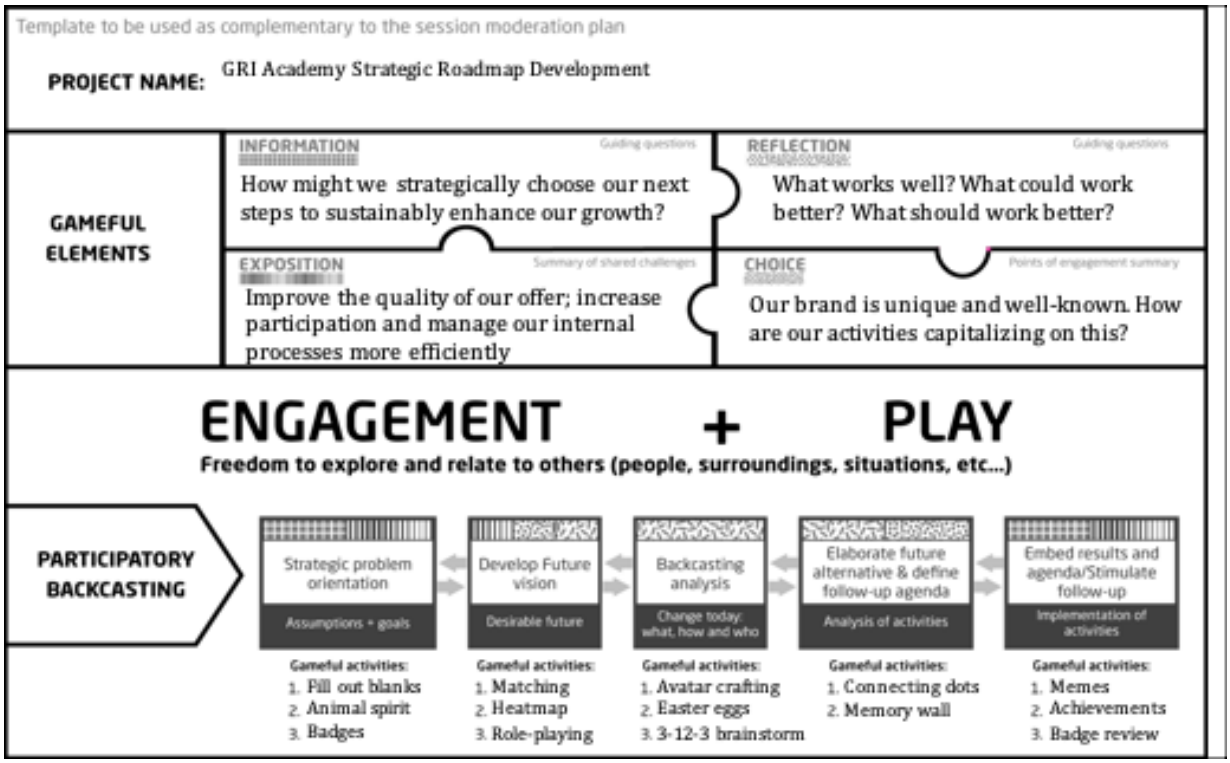

***Figure 3**. GAMEBACK template filled for the GRI Academy online backcasting process*

3. Results

This case explores the online implementation of a fully gamified backcasting process and analyzes the learning that emerged from this experience. Thus, the results are presented and discussed according to the group composition (the players), motivation components, and the implementation methods.

3.1 About the players

The results comprise the work of 10 people from different teams across the organization; the six members of the Executive Team and three members of the Management were involved in different capacities. However, this team did not partake in all the elements of GAMEBACK at the same time. The size of the group for the online meetings played a role in terms of the number of outcomes and even the motivation to engage in more gameful interactions. The larger the group, the interactions were more playful and lively. The group size did not hinder the data collection as the participants managed to reach agreements within the time available.

The feedback round after every online session proved to be very useful for implementing the subsequent group discussion. Furthermore, this flexibility was highly praised by the participants of the process.

3.2 About the motivation components

The participants agreed it was good to have an overview of how far they had moved on the day's activities (progress bar). Moreover, the presentation of how they were progressing through the overall backcasting process was also highly appreciated. It was noted that sometimes the process felt quite long, and it was good to see how they were moving forward.

The sense of completion was shared among the participants during the feedback rounds at the end of each process step. Each of these sessions concluded with a virtual trophy for the team (Figure 4).

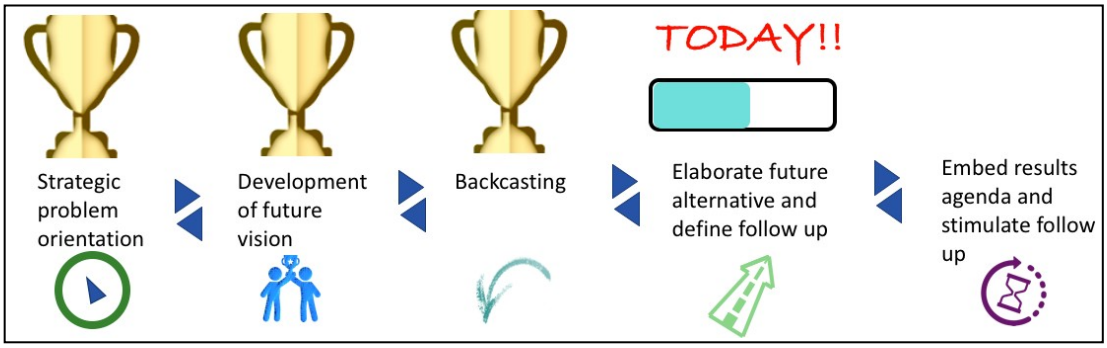

***Figure 4**. Screenshot of progress bar during feedback session*

Only once the groups worked in two teams competing against each other with a timer visible on the screen. It was noted that, while they were well aware of the time available for the activities and that the facilitator was keeping track of it, the visual presence of the timer had a negative effect, as it introduced a sense of hurry, and the participants were left feeling that they might have missed something from their discussions. A sense of urgency drove the team; someone noted, "we are competing against time" (Participant C, 8th session). Therefore, while the use of templates was highly appreciated, mainly when working together using the online platform, the team reckoned that the most important was the possibility to start acting on some of the issues discussed, even if the roadmap was still under construction.

Many of the discussions included observations such as “how did you come up with that?” or “we weren’t aware of this before,” as the participants reviewed the consolidated input of their contributions and outcomes of the research to help to contextualize their input. Having their self-made avatars on the board helped to visualize these discussions; at some point, a participant started adding icons or speech bubbles to her image, and others followed her example.

The team expressed their willingness to overcome the challenges that they had identified as part of their development process and were motivated by the possibility of designing a strategic action roadmap that could help them to prioritize their activities, distinguishing the low-hanging fruits and these actions

that, though desirable, would be better to plan for the mid and the long runs. Despite the increased use of symbols on the board, the most discussed gameful element were the stakeholders developed for role-playing the Academy in the future and crafting the scenarios.

Because of the group's composition, there was a shared keenness to co-create a practical roadmap, ensuring they included all relevant topics and activities and could start bringing them into practice before the year's end. Therefore, the process was driven by the two subcomponents of relationship and teamwork, which were strengthened by the opportunity to socialize while working online.

The application of GAMEBACK online benefits from the gameful elements that enable participants to feel excited about the process, helping to build a sense of community while developing strategies to overcome challenges (that's the objective of the planning process itself). Besides providing the proper sense of completion for each step of the process, it is important to have a connected storyline as the roadmap heads towards a long-term desired future (co-developed during the visioning session). The narrative must be engaging and consistent with what the participants want to achieve. Because of the characteristics of the process, the design elements had a heavier weight for the smooth implementation of the process and the engagement of the participants.

3.3 About the implementation

Tools and design - The lack of an LMS did not represent a problem, as the team agreed to use a repository in the cloud. All the material for the online group discussions was developed using PowerPoint to facilitate the visualization of content, particularly the outcomes of the individual assignments. Most of the interactions online were aided by an online whiteboard that gave more agency to the participants.

It is worth noting that the participants' perception of the gameful elements plays a relevant role in the appreciation of its utility as a motivator (Mekler et al., 2013). During the final feedback round, the participants considered that the presence of badges and a leaderboard was not very relevant for the online strategic planning process; however, they acknowledged these would be helpful features to use in their LMS to motivate students. "They will certainly appreciate the reward; the more they get, the more advanced they will be in the courses" (Participant B, session 12). A similar sentiment was shared concerning the use of memes, gifs, and other aesthetic-related features introduced to create a more playful atmosphere.

Methodology - As the participants worked towards a common goal, the overall experience was driven by a strong sense of cooperation rather than competition. Throughout each online group session, different gameful elements were tested while working on each step of the backcasting process. In addition, the participants were introduced to the methodology before the planning process started, allowing them to raise questions and express their ideas and suggestions from the beginning of the process.

After the first online session, the participants were excited and ready to continue the discussion. However, the time was over, and the group would reconvene only one week later, which some of the participants recognized was a bit of a "put off" since the first discussions were very insightful and lively, "I am so inspired right now!" (Participant C, session 1). Therefore, the participants were invited to channel that inspiration into their individual input sheets, to be used in the next session. With this activity, it was possible to introduce the award system (badges) and leaderboard by acknowledging the work of each of the participants and giving a badge to each of them.

The third online meeting consisted of developing a future vision, which was also the longest session programmed due to the role-playing activity.

This step proved to be challenging for the participants due to several reasons. The ones discussed at the end of the session were:

- the distance of the timeline. The year 2050 was felt as "too far" even though the team agreed on it as a desirable long-term horizon. This apprehension was noted with comments such as "this is so far off, we can't really plan something tangible for this" (Participant A, session 3). Although this perception did not affect the role-playing itself, it did impact the vision, as the same participant noted that the outcomes of this step of the process were "fluffy ."Interestingly, the other session participants cracked a couple of jokes and beckoned this person to keep playing along.

- although the session featured three short 5-minute breaks after 45 minutes of work and one 30 -minute long break, the participants were quite exhausted towards the end of the meeting. It is worth noting that during the feedback round, one of the participants commented that the process could be more "agile" – this is, dividing the work into small batches that could be delivered more quickly. Although each of the steps of the backcasting process was designed as a series of sprints similar to the agile project management method, despite the playfulness, the length session affected the perception of efficiency achieved during the first two shorter and faster-paced sessions.

This finding is an invitation to think about how to enable playful, immersive visioning activities that could take place in shorter time slots. Also, it shows that role-playing works best for large groups or with a very small number of characters. The latter is a shortcoming if the purpose is to bring the voice of all the stakeholders identified earlier in the process.

For the backcasting step, the participants were invited to create an avatar, which was later introduced to all the material showing on screen how they were moving through the process. This activity was considered highly enjoyable, with conversations that ranged from similarities in their chosen outfits to whether to include avatar-making as a feature of their LMS or not. This step was the transition between phases 1 and 2. It introduced the first roadmap draft, which served as a reference for zooming into the user journey, and the Academy as an online educational offer. These elements were analyzed in detail

during the future alternative definition and the agenda creation, which helped review the action roadmap and validate some of the milestones.

During the last two sessions, it was shared that two of the strategic actions deemed as the most critical next steps were already started. The development of the roadmap facilitated the prioritization of tasks, and the people responsible for these particular actions managed to organize themselves to get the processes started. As they were two weeks into these activities, they could provide feedback on the roadmap and include some initial results during the validation workshop with the Executive Board.

Table 2 summarizes the steps of the process and the general feedback and observations collected.

Table 2. *General feedback and observations about the process*

	Strategic Problem Orientation	Visioning	Backcasting	Future alternative and agenda definition	Embed results and stimulate follow up
Sessions	1, 2	3 , 4	5, 6, 7	8, 9, 10	11, 12
Participants' feedback	The discussion time felt too short as there were many topics emerging.	It was exciting and very challenging at the same time.	At points, it felt repetitive as the stakeholder map and the vision were revisited.	Using the online templates to fill out during the discussion and having new participants helped to see things from a different perspective.	"We have already started with…" The team was keen on seeing the final roadmap.
Observations	The participants had already talked about these issues but this was the first time they were putting them together "on paper".	Session 3 was the longest of the entire process (3 hrs) and session 4 was designed to conclude this step of the process.	The transition to Phase 2 started on this step introducing new team members into the process.	The introduction of the Academy's users' feedback and market analysis led to revisiting the vision and the milestones. The roadmap was thoroughly reviewed.	As some of the planned activities were already taking place, the roadmap was welcomed as a visualization of their "to do" list.

Process results – because of the two-phased approach, the structured roadmap with milestones for the short and mid-terms, was already in place by the time that the second phase kicked off. Besides the vision, the scenarios and the strategies, the team also developed a competitor analysis, a user-experience

map and a learning journey plan. By the time that the process ended, the GRI Academy website already featured some of the changes featuring in their plan.

4. Discussion

The pilot study sheds light on some potential shortcomings and possibilities for improving the application of GAMEBACK as an online experience. After a year of online interactions, the participants welcomed the novelty of the approach presented. Even though the overall process consisted of only 32 hours online spread across five months, towards the end of the second month, some participants observed that the offline, individual input was too time-consuming. They would prefer more online teamwork together to save time. This format was explored when the content allowed to do so. Although the discussions were lively and productive, the fact that new team members were joining the process also led to returning to the individual work prior to the session and spending the online sessions working on the consolidated content of the individual input sheets to formulate joint decisions.

Limitations: Although the participants enjoyed being awarded a badge and always commented on their standing on the leaderboard, they also noted that the process could have worked just fine without these additional elements. One reason behind this is that the team had a very clear objective in mind, so they did not need any additional motivator. However, the participants also expressed their interest in introducing a badge system for their students as they found the overall experience quite exciting. Moreover, their LMS's elements include a dashboard with individual progress tracking, badges, leaderboard, and discussion groups. All of the elements that the group piloted as part of the user experience. While the user-centered design approach proved its value in developing and implementing the process, the principal researcher spent on the content development, collecting individual inputs, processing the results, and consolidating the outputs exceeded the time initially allocated for these tasks. One reason for this is that 80% of the material was developed from scratch, usually building upon the outcomes of the group discussions; however, the template development time was reduced once the whiteboard software, which includes a collection of templates for different types of analyses, was introduced. The facilitator plays a crucial role in keeping up the implementation of the gameful affordances according to the desired outcomes of the backcasting process and in managing any technical difficulty or any other unexpected challenges.

The application of GAMEBACK as a MOOC-styled interaction offers many advantages for educational and organizational purposes. First, it helps to design the interactions among participants as close as possible to the setup where the action plan will be implemented. Such design aims to allow the participants to immerse themselves in the position of their intended users, thus identifying opportunity and challenging areas that they can already address without waiting for the users to bring their attention to them.

Reflection: The design process also allowed the necessary flexibility to reschedule some sessions when necessary, something that the participants welcomed. The technical aspects also played a role in the

time allocation, both when interacting online and for the offline processes. Having less but more versatile tools may help overcome the challenges related to access to information, online interactions, and overall coordination of activities. Bearing in mind the factors related to implementing the process, developing a badge–leaderboard system is recommended for further implementations of GAMEBACK online, particularly when bringing together representatives of different units of the organization or diverse stakeholder groups (Mekler et al., 2013). Some of the advantages of working with such a small group include the possibility of in-depth discussions and even getting to know each other. The latter was highlighted as one of the most important outcomes of the process since two people new to the organization joined during the second phase. "These discussions helped me to not only to get a very detailed 'big picture' but also gave me the possibility to get to know people I am not sure I would have talked to in other circumstances" (Participant D, final feedback session). While the strategic roadmap could have been developed without the gameful elements, the participants welcomed the approach as it was different from any other online interaction they had. "The dynamic spirit of our sessions made the whole process a time well-used" (Participant B, final feedback session); "I am looking forward to our weekly discussions; they are interesting, fun, and very insightful. Most of the time I wished we could spend more time discussing, but I am very thankful that you listen to our suggestions for improving the content and give us time to talk" (Participant C, Session 8).

Broader relevance and contribution: This implementation of GAMEBACK online is the first of its kind, and it serves as a stepping stone for further development in the areas of online, gamified strategic planning processes, particularly backcasting. The results presented offer ample room for improvement; they provide a basis to develop material that can be adapted to different stakeholder groups and setups; moreover, they present backcasting online as an enjoyable activity that can yield substantial results.

5. Conclusions

This study explores the experience of designing and implementing a fully-gamified backcasting process online using GAMEBACK, a gamified backcasting framework, to facilitate the strategic planning process of an organization offering online training for sustainability reporting. The experience consisted of applying different game-like elements designed to motivate users of online games throughout the entire online backcasting process.

The feedback collected during and after the implementation process helped provide a detailed overview of the participants' impressions, experiences, and overall motivation to remain engaged in realizing the goals they set for the organization, particularly for the short and mid-terms. Therefore, the presented best practice interprets the experience expressed by the process participants, from the first discussions to the design of the delivery system to the very last feedback round. The latter included the reflections after the validation workshop with the Executive Team and the presentation of the final strategic roadmap, which was already underway by the time the process ended.

Despite some of the initial limitations, such as the time between sessions, participants' regular activities, and internal deadlines, the overall experience was positive for everyone involved, particularly because, acknowledging the presence of the gameful elements, the participants enjoyed the planning process and are satisfied with the results achieved. The team feels fully responsible for the outcomes of the process and is actively working on the implementation of their action plan. There is a stronger sense of ownership, and by the time this article was completed, several of the strategic activities established during the backcasting process were already underway.

Gamifying the entire PB process to implement it online may be challenging for projects with very tight deadlines or large groups. However, involving some of the participants in the design of the process, inviting them to see themselves as players of an online experience, helps to present this particular online experience as a break from the all-too-familiar online interactions that demand high levels of attention for listening and looking to a screen all the time.

Through this study, the case of a fully gamified online backcasting proved appropriate to motivate the participants from different units within an organization to keep engaged throughout the process and put themselves in the shoes of their users. While face-to-face interactions are still desirable, the possibility of carrying out parts of the gamified backcasting process as an online activity, a hybrid backcasting approach, is also open to exploration. The material, experience, and best practice of this first online implementation lay the groundwork for designing and implementing fully online or hybrid backcasting processes.

Fostering Narratives through Arts-based Research

A methodological exploration

Kristen M. Snyder[1] and Elizabeth Turesky[2]

Abstract

Culture has been central to societal development for centuries as an experienced-based event, and a catalyst for change. Culture is now recognized as a fourth cornerstone for achieving sustainable development. This paper contributes to the ISDSR Agenda on culture and sustainable development through the lens of qualitative research methods. Specifically, this paper explores methodological possibilities and implications to apply arts-based practice as a dialogic tool to foster multiple narratives, the inclusion of voice, and diversity of perspective contributing to Track 1B.

Qualitative researchers continue to push methodological boundaries to study social phenomena. Among the methodological developments is an exploration of the application of the arts. Research methodologists suggest that the arts open new possibilities in research through the very nature of the arts to stimulate and evoke perspectives. The arts promote dialogue which yields new insights; highlights multiple meanings, opens space for diversity, and questions norm-based traditions. The purpose of this paper is to present findings from a duo-ethnography to explore the application of the arts as a dialogic-reflexive process during the data analysis phase in qualitative research. Findings contribute with concrete insights into how science and culture can be combined as a methodological approach to garner perspective and invite voice to achieve sustainable development.

1. Introduction

For centuries, culture has been central to societal development, reflecting life, stimulating thought, and challenging the status quo. Culture is now recognized as a fourth cornerstone for achieving sustainable development (CAE, 2020). The Culture Action Europe (2020) states that "culture offers exploratory, interrogative, and critical approaches to the world and its systems, and nourishes the ability to identify and analyze current and complex challenges that need transversal and multidisciplinary responses to be understood and acted upon. But above all, culture is the common good, its gain is fundamentally social and collective, contributing to the creation of equal, diverse, and supportive societies" (p. 1). The inherently social nature of the arts holds promise for individuals, organizations, and communities to develop a new language through which to socially construct (McKinley, 2015) a sustainable and shared future.

The Creative Clash (KEA, 2011) suggests that "culture-based creativity…is a driver of innovation, social well-being, and inclusion. It is through the process and ability of art to

Schiuma (2009) arts-based experiences create an environment that frees people from traditional ways of seeing and working by moving them out of their comfort zone, creating space for reflection, and making the invisible visible (Carlucci & Schiuma, 2018). The experiential nature of the arts stimulates learning in unique ways expanding the focus from cognitive knowledge to include embodied knowledge (Nissley, 2010). This broader approach to knowledge development expands the ways in which we understand and shape meaning through co-construction. Lee et al, (2018) highlight the numerous studies that examine the value-added from the arts in business, They suggest that arts-based initiatives are now recognized as powerful tools that can help organizational members and leaders to think outside the box and stimulate value co-creation and sustainable practices (i.e. Carlucci & Shiuma, 2018; Nissley, 2008; Lee et al, 2018; Berthoin, et al., 2016). Such developments invite questions about how the arts can be applied in a variety of social settings, both formal and informal, to encourage multiple perspectives and co-creation/construction of experience through which meaning is derived.

In the field of qualitative inquiry, the arts have been explored since the late 1980s as a tool for data collection and representation. As a research method, arts-based practices use the expressive qualities of the arts to awaken and convey meaning (Barone & Eisner, 2012). Research methodologists suggest that the arts open new possibilities in research through the very nature of the arts to stimulate and evoke perspectives. The arts play a critical role in helping us understand that there are multiple answers to a problem or question; life is not necessarily linear and absolute (Eisner, 2002). Godfrey (1992) writes that "art plays an integral role in civilizing a society and its members. If introduced early and incorporated regularly into instruction, art teaches us about our capacity to communicate ideas and feelings in a variety of modes and media; to analyse data through analogy and illustration; to accept compromise, ambiguity, and difference as positive human traits, and to construct ethical standards of judgment and action...Art is amazingly inclusive as an uninhibited entity in society" (1992: p. 596-597).

Many examples of ABR exist in which the arts are used for either data collection or data representation. Less developed is the use of arts during data analysis phase in qualitative research. The use of the arts during the data analysis phase is a critical gap in the methodology literature that needs attention. The interpretative nature of qualitative data analysis requires that researchers set aside their assumptions and open space for the voices and representation of the study's participants (Patton, 2002). Critical theorists and feminist epistemologists have argued for decades about developing a praxis in qualitative research that de-privileges the researcher's role, thus emancipating the study's participants (Lather, 1991). According to Brookeld (1995, in Brown & Sawyer, 2016), "we are our assumptions"; consequently, "becoming aware of the implicit assumptions that frame how we think and act is one of the most challenging intellectual puzzles we face in our lives" (p. 2). Using arts-based methods to create interactive spaces that evoke embodied experience may provide researchers with tools to make visible assumptions and challenge those assumptions.

dialogic- reflexive process during the data analysis phase in qualitative research. Two professors in academia, also professionally trained artists (a dance and a musician), conducted the study. Interest emerged when one of the researchers questioned the validity of their analysis to give voice to the study participants. Findings contribute concrete insights into how science and culture can be combined as a methodological approach to garner perspective and invite voices to achieve sustainable development.

2. Background

One of the unique elements of Arts-based research (ABR) is the opportunity for researchers to disrupt perspective through their participatory practice and re-conceptualize perception from their new embodied experience. The arts promote dialogue through embodied knowledge (Tanaka, 2011), highlight multiple meanings, and question norm-based traditions. This is important for creating new architectures of dialogic-reflexivity to give rise to voice. Engaging in dialogue, that is based on reflection and self-reflexivity (Hertz, 1997) creates consciousness about who we are in relation to one another, including our ideological perspectives, cultural backgrounds, and the like. In so doing, we expand our collective space and invite room for multiple voices to be present and represented. Through a shared experience, possibilities to disrupt the dominant discourses (Bruner, 1986) are made possible.

The dialogic nature of ABR is now promoted as a fourth essential practice in ABR to stimulate critical thinking and reflection, value social construction, and foster voice. Through participatory practice, researchers can re-conceptualize perception from their new embodied experience that involves dialogic reflection (Rashid, 2018). Bakhtin (1986) contends that dialogue can serve as an important framework for knowledge construction. Moreover, Brown and Sawyer (2012) argue that dialogue is important to move acts of reflexivity from the solitary to the collective, suggesting that new perspectives can be stimulated through interaction. The key to dialogic reflexivity in research is in new structures that emerge during the research process. The interactive nature of embodied knowledge that emerges through the arts provides a vehicle for research to challenge assumptions, both in terms of data collection, analysis and representation.

Leavy (2015) explores the array of artistic forms and their application to research. In this paper, we highlight music and dance to reflect our own artistic backgrounds applied in this study. Music's role in society has been central for centuries, serving as a social function as well as in healing (Stevens, 2012). Music is also used in education to stimulate learning, facilitate expression, and develop skills in listening, collaboration, and teamwork (Snyder & Cooper, 2015). Musicians have a unique ability to listen and interact with sounds (Rostron, 2003; Sorsa, et al. 2018). They are trained in fine-tuning their listening skills to identify small nuances. As Leavy (ibid) suggests, "music-based approaches to research can help researchers access, illuminate, describe and explain that which is rendered invisible by the research practices" (p.128). She quotes Huxley who said that 'after silence, that which comes nearest to expressing

Bresler (2005) sites that music can help researchers build their listening skills, which is essential in qualitative research. The language of music, based on melody, harmony, rhythm, tonality, form, and dissonance can be transferred to everyday settings to help researchers fine-tune their skills in listening (Bresler, 2005; Snyder, 2019). Leavy (2015) suggests that the components of music can help qualitative researchers enhance their perception, conceptualization, and communication. She also recommends that researchers consider the above categories when analysing interview data.

Dance is another art form that can serve well research methodology according to Leavy (ibid). Like musicians, dancers use form, structure, and rhythm to express themselves. As a form of knowing, dance has been described as physical thinking; a process of using the body as an instrument of cognition (Kirsh, 2011) Muntanyola-Aura and Kirsh (2010) talks about the unique interaction that the body and mind can offer a thought. In their words, the body can serve as a "simulation engine or as a representational system, that allows a thinker to interactively formulate thoughts about a domain. Thought can be more body-centric (p. 1). Leavy (2015) refers to the work of Clark-Rapely (1999) who suggests that dance "is a form of transformative human action that expresses an individual's being…and can thus support, rather than alienate communal relations" (Leavy, p. 159).

Combining music and dance in a duet enrichens the embodied experience through the interaction of different forms of expression. The use of a duet, as performed by distinct art forms, adds perspective in unique ways. It stimulates a dialogic-reflexive component, that can strengthen the researcher's the ability to challenge assumptions that lie within their own perspectives. Both music and dance use form and rhythm to express and communicate. Dance also introduces movement to the duet while music introduces tonality and melody. Interacting in this expanded space opens the possibilities to stimulate thought and develop a more complex interaction that may serve to reflect the complexities embodied in human experience (as derived from the qualitative data). In so doing, the improvisational duet has the potential to become an embodied act of dialogic-reflexivity.

3. Methodology

The study presented in this paper is an embodied research study (Finlay, 2014) based on a Duo ethnographic methodology. Duo ethnographers seek to generate new perspectives about a topic through the interaction of differences: "Rather than reaching a consensus, duo ethnographers make their disparate opinion explicit" (Norris & Sawyer, 2012, p. 14) and in doing so attempt to disrupt the metanarrative "by questioning held beliefs" (Norris & Sawyer, 2012, p. 15). Duo ethnography is an emerging methodology that intentionally juxtaposes multiple perspectives to de-center preconceived notions of reality. The researcher's background is used to probe, explore, question, and stimulate perspectives around the research data (Norris & Sawyer, 2012). With this form of personal inquiry, two researchers investigate a topic of interest using their own life as the

interaction, and reflection are central to the methodology to stimulate new insights and understandings.

As researchers, we are both academics and artists. We are Professors in leadership and organisational development and quality management. One is a professionally trained dancer, and the other is a professionally trained musician. The common knowledge base for the experiment was leadership studies and artistic expression. The point of departure was qualitative interviews conducted by one of the researchers in a separate study that examined what women in high positions of leadership experience during their rise to the top. The other researcher was not privy to the interview data and thus served to interrogate perspective from a distance.

The experiment was carried out over a two-day period during which improvisation and reflective dialogue were integrated. The experiment was guided by the question, "how can embodied knowledge (as created through music and dance) inform a deeper understanding of the concept, "Deviance", which was identified in the initial qualitative analysis of the interview data. Two practices were included in the experiment: 1) Free improvisation, and 2) dialogic as reflective practice. Improvisation is the creation of something without a pre-conceived plan (Nunn, 1998). Self-reflexivity is a process used by researchers to mediate the balance of position between the researcher and researched to lend voice to the respondents (Russell & Kelly, 2002). Dialogue is defined as a conversation without sides (Isaacs,1999). It reflects a communication paradigm in which "process" is given more weight than "outcome".

The improvisation was approached as a dialogue between the flute and the dance. The function of the flute was to listen in, feedback, mirror, and challenge what was performed in the dance. The function of the dance was to express different aspects of the stories shared by the interviewees that reflected their journeys to high positions in leadership.

Four dances were completed and recorded. The first two dances (warm-ups) lasted between three to five minutes in length. The second two dances (reported in this paper) lasted between seven to fifteen minutes. Following each dance, a reflexive dialogue was held during which we explored our embodied experience as it related to examining more deeply the qualitative research data from the interviews. We worked to understand each other, what we were experiencing, communicating and what more we might need to add to our free improvisation to take us into the deeper levels of data analysis with the interviews. Among the elements, we explored were space, rhythm, listening, and collaboration. Of significance was to understand how our different artistic forms could be in dialogue with one another and integrated to support the analytical process.

4. Results

In this paper, we present findings from two of the improvisational dances that focused explicitly on the concept of deviance as a construct among women who had achieved high-level leadership positions. The construct had been identified by the dancer in this study during a qualitative

The Deviance Improvisation part 1:

To get inside the stages and experiences that the women leaders went through to achieve their high appointments over the years, the dance began low, on the floor, spiralling up over time to reflect the stories of the women interviewees and their rise to power. The spiralling elements reflected their non- linear journeys. The music began on the lowest tone of the flute and meandered up the scale, slowly, spiralling with the dance, interacting with the movements as they emerged, becoming intertwined. At times the dance returned toward the floor representing elements of the backlash to success that many of the interviewees experienced along their journey; reflecting once again the non-linear dimensions for women to achieve positions of power.

As the dance progressed, wandering sideways and upwards to success, the tonality in the music shifted from one of a heavy burden to lightness and inspiration reflecting the inner strength that was evident in interviewees' stories. The dance began to reflect the steps that the women leaders took on their journey to rise through the ranks emancipating their power. Pushing through power plays, moving barriers, claiming space.

Figure 1: excerpts from the first improvisational dance

The dance ended with upward movements and large steps forward that reflected a sense of arrival shared by the women leaders when they had achieved a certain position in the ranks. And the end of the dance we both found ourselves inspired to want to climb more and continued spiralling upward. The dance ended after 5, 37 seconds. We paused for a moment, soaking in the experience. The dancer (Liz) began to feel that she was entering the data but needed to have more with her if she was going to dig deeper into the complexities of deviance. After further dialogue and reflection, she stated, "Let's work with the concept of encounters. I feel the need to get more percussive. Aggressive. Assertive. I think these ideas can help me get inside the concept of deviance, which I perceive is a part of the experience for women in high leadership positions; that they "deviated from the norm to get to where they are today."

The Deviance Improvisation part 2:

And so began the dance for a second time. Just like the first dance, this second iteration also started from the floor to represent the journey of the women in leadership. Yet this time with more focus on the theme of encounters. The dance evolved around the elements of struggle, communicated in more percussive gestures, and deeper emotional movements reflecting frustration, fear, at times confusion, questioning, and testing possibilities.

Figure 2: excerpts from the second improvisational dance

The music followed the rhythm of the dance more closely this time, speeding up with quick movements and slowing down with softer movements. When the moves were directed upward, so too followed the music. This close interaction with the music mirroring the dance was intended to give space for reflexive improvisation as the dancer navigated insights into the themes of encounter, percussive-aggressive- assertive.

Figure 3: excerpts from the second improvisational dance reflecting themes of encounters

After 5 min and 43 seconds into the improvisation, Liz stopped abruptly, looked, and said: "I need to make noise!" And she started to stomp on the floor in a percussive dance as she grasped her fits and pounded against the air above her head. The flute followed with a crazed melody, bouncing off the percussive steps of the dancing feet, and the wildly swirling hands. The percussive gestures repeated themselves, each time with new facial expressions that illuminated a sense of inner craze.

Figure 5: excerpts from the second improvisational dance reflecting dichotomous emotions

After the third such gesture, the dance turned toward a kind of resolve: the energy of frustration had been identified and released. The movements began to spiral back down through a series of flighting gestures that ended in a calm. The flute followed as the arms extended softly while the body continued to spiral out of the percussive encounter, landing in a sense of peace and calm. The movements became elongated as the dancer circled through the entire floor space with strength, reflecting a kind of empowerment that appeared to engulf the women in leadership in the study. The dance ended shortly after (at 7, 23 minutes), and there began our most profound reflection which also served as the pivot point in the analysis.

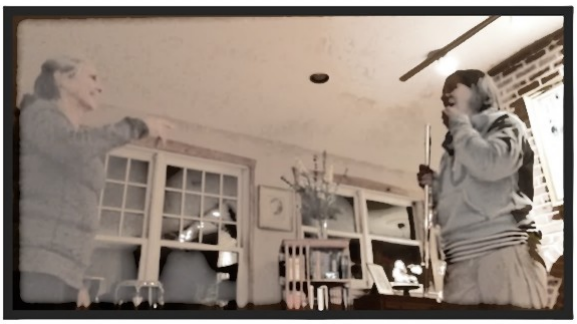

Figure 5: reflective dialogue after an improvisational performance

"There is something missing, I am not being honest". Reflected Liz. There is something that I really couldn't express. Could you understand that while I was dancing?"

Wow, that's interesting. I think so. I found myself playing in a chromatic scale for a while and then I realized that I needed to change my own playing as a way to also help you to come out. I saw that your gestures were ready to move out and expand to celebrate the women's power. If I were to write the music to it, I think it would be similar to Aaron Copelands Appalachian Spring where the music just opens up.

"Yeah I felt too", shared Liz "it was really a sense of freedom to be whoever you are, where ever you are. That's one of the powerful findings from the data that I began to see more clearly. ".

I also realized for myself that I couldn't dance out something like "Deviance" by myself. I needed to push against someone. In the process, there is a lot of misunderstanding; hurt, and fear. I was trying to do the experimentation. But I couldn't get to it. Part of it was that the music didn't feel like it fit the deviance that I was feeling inside. That was a place perhaps where the music could have stopped. I could have just pounded out alone because there is nothing gentle about that. The other thing is that I don't dance percussive. I was thinking of pulling out the drums (which were in our space)

This is interesting. What you are describing is a typical perception of what is deviance and how it occurs.

Yes, I think so. It feels like it is how it would be to be deviant. I was thinking about people who are deviant in society as I was dancing.

My question to you is, what if that's not what women in high positions actually go through? What if there is another picture in the data that is not illuminated because we are guided by that one perspective (traditional) of deviance. If we keep the traditional notion of deviance we assume that the women in your study must have gone through hell, must have gone through a battle. But did they?

Yes, some of them really did. Some of them didn't. Some talked about being moved into positions of power because of their networks.

You described in your dance needing to have something to push against. Did the women also describe things that they pushed against?

Yes, like husbands. But some of them weren't willing to share those kinds of details. They just talked about the straight path and mentioned there were battles, but not what they were.

It's interesting to hear you reflect on the improvisational process and how there were parts that didn't work for you or some elements that were missing

Some parts worked for me.

I am wondering if there might be something more to examine. Can we ask questions about the things that were missing for you in your dance, or that didn't work for you? Perhaps we can identify new questions that you can bring to your analysis?

That's a good question. And what you asked me about "did all the women go to battle" is one of those kinds of questions. And did they feel they were getting out of a comfort zone? Did they feel free? When you discover that you are not the norm, what happens?

….

Our conversation continued along this path to explore the concept of "being different". Over time, the dialogue moved back to the start of the conversation, to deviance, recognizing that the concept of deviance needed to be further explored and considered from multiple lenses. We also returned to our improvisation to understand it more deeply, including perhaps hidden elements that we didn't consider and their potential implications to explore deviance. Liz began reflecting on different movements that she could have chosen to explore more in-depth her own inner experience with the concept of deviance. We began to re-interpret some parts of our interaction that we initially determined to be problematic.

If we go back to our improvisation, the music tried to follow the dance. At times it was disturbing because it wasn't in sync with, for example, the stomping. But how might that music then represent something else that is a part of the bigger picture?

Yes, the music that was playing was a kind of constancy. The world goes on, and here I am stomping, but the music kept going.

Yes, that rights, and that's how it should have been. I just should have kept going and stomping and been even more out of sync with the norm (a sign of deviance).

We began to reflect on the experience and power of improvisation to access emotions, assumptions, and perceptions. It became an analytical device embedded within an ethnographic study, that stimulated us to ask questions of one another, of our interpretations, and possible alternative interpretations as well.

How about you? You weren't playing deviance. How would you do that? Liz asked.

If I think about deviance, and I take the flute and it has pureness in its sound. We expect the purity to be there, we expect the melodies to be beautiful. If I were to play deviant, I would alter the expectations that we have for the flute. Change keys in the middle unexpectedly. Use tonal experimentation to create a harsh sound.

And then that would be it "deviant" until you are comfortable being out the circle, then you are no longer deviant." Liz reflected

> *"I think to have deviance in music, you need to have percussion. You also need to deviate from the form".[reflective pause] "Another thing is that there is an assumption that deviance isn't beautiful. But if we think about some of the great artists who didn't follow the norm, they created beautiful art, but it deviated from the norm of acceptability."*
>
> *This is interesting. There is an assumption that deviation is harsh and tough. But you can deviate from a musical scale, and it becomes something different, but it still has beauty. When we don't understand the scale, we perceive it as 'wrong' or 'false'. Yet when it is something, we recognize, it no longer deviates from our own personal norm and expectation", I reflected.*

5. Analysis and Discussion

In the analysis, we highlight five key insights drawn from the experiment to understand how the arts can be used in research to foster multiple narratives and stimulate deeper awareness of alternative perspectives. Among the five insights highlighted are 1) curiosity and questions serve as a guidepost for improvisation and exploration; 2) Test improvisational forms and negotiate a collaborative space; 3) Building reflective dialogue into the improvisational space; 4) Dialogical reflection as deep learning requires time and structure; 5) Journaling promotes dialogic reflexivity and deep learning

Curiosity and questions serve as guideposts for improvisation and exploration

The experiment in "deviance dance" showed several key elements that were important to both process and transformation of thought. The process was guided by curiosity and question. The curiosity was to explore how we might use our artistic forms of expression (dance and music) as a vehicle to interpret qualitative interview data that gave space for voice and multiple perspectives. The question behind this curiosity was derived from the research setting in which one of the researchers articulated a need to probe the multiple perspectives in the voices of the respondents in new ways. The curiosity and the need became the guideposts within which the architecture of our experiment was shaped. Asking big questions, getting curious, and staying open to possibilities are significant to frame strategic thinking and innovation (Brown, et al. 1999; Brown & Isaccs, 1996). It is through our questions and getting curious that we are stimulated into reflection dialogue and reflection (Bohm, 2004)).

Test improvisational forms and negotiate a collaborative space

Combining artistic forms (music and dance) in the research process was new to both of us, and as such, it required a phase of experimentation. The first two dances were performed as pure exploratory improvisations during which we developed an understanding and praxis for how we would work together. Among the key insights were 1) the need to frame the dance with a particular research-based question. When the music and dance were combined without a probing question, it became just another dance. Connecting the arts and science needs a common denominator. 2) the need to understand the interplay between the different art forms and their role in the non-verbal

interacting with a third dimension. The musician was interacting with the dance. This raised questions about how the decisions we make (i.e. to take a breath, to stop a movement, to change the rhythm) impact each other. This is a standard component of dialogue in which we interact with one another's words (Isaac, 1996), intonation, rhythm, and the like. When the words are missing from the dialogue, we need to develop new spaces in which to interpret and understand one another. 3) Understanding space, what it is, and what role it has in dialogue and reflection is important. Space can be conceptualized and communicated differently in the arts. For example, in painting and sculpture, black and white create a spatial balance.

In dance, movement and stillness are used to create space and in music, sound and silence create space. The inquiry into the movement in space and time can open to reflections about how we as researchers cause others to move in our rhythm, and our perceptions.

Building reflective dialogue into the improvisational space

The dialogue was an integral part of each dance. The dialogue and reflections tended to be unintentionally guided by the focus of the dance. For example, in the first two dances in which the focus was on developing an improvisational process, the dialogue reflected the experience of partnering to create a common language for communication. In the latter two dances, the reflective dialogues focused on digging deeper into our interpretations around a research theme and drawing on theoretical knowledge as well as embodied knowledge.

Dialogical reflection as deep learning requires time and structure

Building on a previous improvisation enabled both of us to deepen and enrichen our exploration of the data, this time adding to the pot the new themes. Combining embodied experience through the arts with deep reflection can serve well the concept of deep learning promoted by Senge (1994). This kind of deep learning, Senge et al (1994) claim, takes place within a particular architecture that includes 1) guiding ideas, 2) innovation in infrastructure, and 3) theory, methods, and tools. The guiding principles include systems thinking that we are all a part of a larger system and we do not need to create inter- relationships for they already exist. The second principle is the "community nature of the self", which suggests that individuals are a part of a larger culture; we are talking about the collective when we talk about the self. The third principle is "the generative power of language", arguing that we co-create our realities through our own understanding of experience.

Journaling promotes dialogic reflexivity and deep learning

Journaling about what was learned was an essential part of the process, no matter the form. In our experiment, we both used different types of journals. Digital journaling was used to capture the dialogues and improvisational performances. Text-based journaling was used after the improvisational space to further explore the embodied experience further and arrive and new insights and knowledge. The continuity of journaling both during and after the event created a space for continued reflection, which when shared with others served to stimulate new insights and understanding of multiple perspectives.

6. Conclusions

The five insights shared above reflect some of the key learnings that we draw from the Duo ethnographic study of the improvisational dances. They suggest ways in which the arts can serve as a dialectic tool in qualitative data analysis to provoke an awareness of assumptions and perspectives. Based on our experience, communication was expanded through the arts, to include both verbal, non-verbal, cognitive, and embodied knowledge. Immersion in artistic creation, we suggest, establishes a deeply reflective space that is transferable beyond research. Such an experience can offer conditions for time and space to stop, pause, create, and reflect. When facilitated skilfully, such a space, allows people to open to a deep exploration of their own perceptions, practices, and their root influences.

Among the interpersonal dynamics explored through artistic practice in this study were aspects of space, in relation to others, and in our case the object of study. The arts-based practice created an architecture within which to explore this space. Transferring the dialogue to a collective experience, stimulated new awareness about our spatial relations to one another: how we impact each other and are impacted by one another. This is a critical skill to develop as a global community to develop cultural sensitivity and develop behaviours of appreciation for difference and community. This also has strong implications for role relationships in dialogue and the art of listening (Snyder, 2019). How we develop an interactive balance between one another so that no one voice has power over the other is a contemporary and future challenge to achieve equity and democracy for a sustainable future.

The dialogue that took place during the improvisations included a conscious commitment to diversity and voice. We were keenly aware that we needed to develop a praxis to open our minds to consider different perspectives; to shake our assumptions. As a human race, one of our greatest challenges to achieving sustainable development is developing consciousness about how we relate to one another and value each voice. The arts can provoke us into awareness as we become the instruments and art forms that make up a collective rhythm, shape, and movement. Sustaining this, however, will require that we develop an architecture that fosters non-judgemental dialogue and reflexivity.

Culture is an integrated part of our local and global society. As a social praxis, the arts are used to reflect espoused values, challenge perspectives, and represent thought, among other things. Culture is also ladened by questions of access that have stimulated debate for decades. Revisiting the contemporary global challenge for culture to serve as the fourth dimension toward sustainable development suggests the need to explore the ways in which the arts can be expanded and applied in a variety of social settings and institutions to make them more accessible; not just as a reflector of society, but also as a forum for social constructivism to emancipate voice and approach equality. Integrating social constructivism through art initiatives involves a specific methodological design and strategy. It is also important to note that one need not be trained in the arts to invoke the arts in

power to transfer the language of the arts to every life and everyday setting.

Combining the creation of art, discussion, and reflection together offers participants experiences that embody significant social, psychological, and developmental dimensions. Engaging in an artistic participatory process invites an experience-based object against which to reflect. The shared experience, if cared for, has the potential to shift power imbalances and promote social constructivist spaces. The space needs to recognize the common experience and the unique relationship that each one of us may have to the experience, colored by our own backgrounds and perceptions. Meeting at the crossroads of our shared experience can enrichen our collective awareness and open space for multiple voices and perspectives. Arts-based practices have the capacity to remove the "I" from the equation and shift focus to a common space in which equality and democracy are bred and sustained.

Exploring the knowledge of sustainable development: Overview of ready-to-use methods with a life cycle perspective

Introduction

The United Nations Sustainable Development Goals aim to boost sustainable development. Life Cycle Sustainability Assessment (LCSA) methodology has been pointed out not only as a way of assessing the sustainability performance of the value chain but also as a tool to enhance circular economy and industrial symbiosis in the manufacturing sector.

Goals

This study aims to perform a systematic review of the application of LCSA methodology to case studies. The goal is to identify the main trends regarding the Key Performance Indicators (KPIs) and methods - for the Life Cycle Assessment (LCA), Life Cycle Cost (LCC), and Social Life Cycle Assessment (S-LCA).

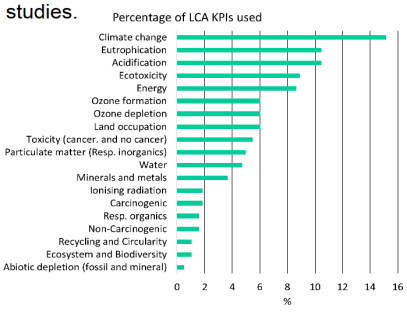
Methodology

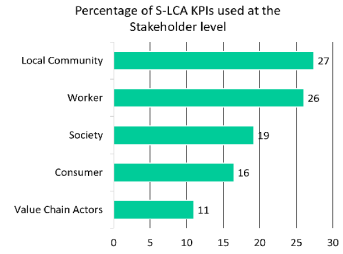
The scientific literature research was conducted on Scopus. The keywords used were Life Cycle Sustainability Assessment" in the title, abstract, and keywords and the use of case study(-ies), for studies published between 2018 – 2021. Among the results, studies neglecting one or more dimensions of sustainability were excluded from the sample. A total number of 53 scientific studies are included in the analysis (a total of 55 case studies).

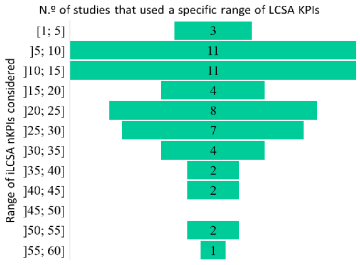
Results & discussion

The authors identified a common trend regarding the most reported indicators (e.g., climate change for the environment, production costs for the economy, and local community and worker stakeholders for the social). The number of indicators strongly differs in each case study (e.g., varying between 3 to 60). However, most studies used 5 to 15 indicators. No consensus was obtained regarding the communication of results; some studies analysed each dimension of sustainability separately, and others, usually the studies with the higher number of KPIs, single score values.

Regarding the sector, most of the studies focused on the energy sector, followed by food, construction, and transportation. The manufacturing sector only accounts for 5 studies.

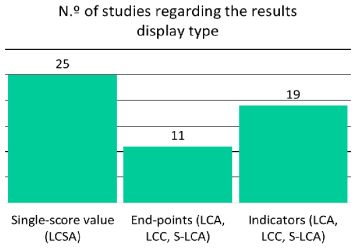


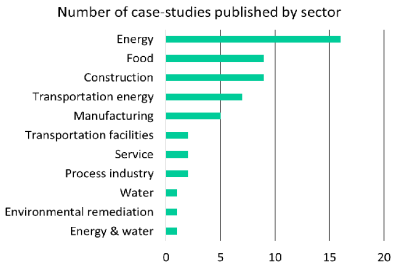


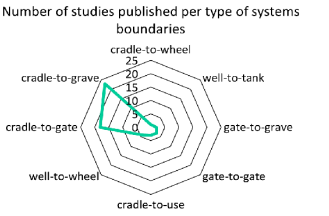


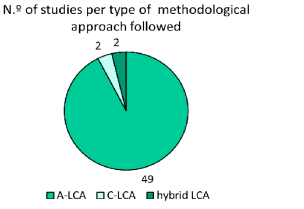
Another finding related to technical details suggested that despite the fact that most studies aim to accomplish broader system boundaries, i.e., cradle-to-grave, this life cycle thinking was only fully applied to the environmental dimension, to some extent to the economic and poorly to the social dimension. Mixing different system boundaries in the same case study can induce gaps in the results obtained, and consequently in the identification of hotspots for further improvements.

The methodological approach for the majority of the case studies relied on the Attributional LCA.









Conclusions

To avoid mixing different system boundaries and provide timely and robust conclusions for the decision-making process it is recommended that the LCSA should be conducted, in the first instance, in a gate-to-gate approach. In conclusion, current efforts are still being made in the robustness and standardization of the LCSA methodology, namely in the development of a normalized framework for the economic and social analyses.

An urban metabolism approach to sustainability in the city of Östersund, Sweden

Introduction

Urban Metabolism (UM) is a metaphor that allows us to look at the city as a living organism. Just like an organism, the city requires food and water for its existence and turns them into wastes. Having information on how much of certain material is flowing in and out of the city can create a picture of its efficiency and sustainability. In 1965, Abel Wolman put up an urban metabolism model for a hypothetical North American city of 1 million people, evaluating some material in- and outflows [1].

As a start for UM research in the city of Östersund, located in the mountains of mid Sweden, a small literature review accompanied with a first assessment of the metabolism of the city were performed [2]. Two research questions were formulated:

- How has research on urban metabolism developed?

- What are the major material and energy flows in and out of the city of Östersund?

Literature review

The UM concept has been further developed since the first attempts done by Wolman and others. The literature review shows the development of different approaches to UM regarding 1) Internal and circular flows [3]; 2) consumption patterns, e.g. the ecological footprint approach [4]; 3) environmental impact, e.g. LCA [5]; 4) ecosystem approaches, based on an energy backbone, e.g. emergy accounting [6]; 5) spatial aspects addressed with GIS assessments [7]; 6) urban planning and design approaches [8]; 7) social-industrial ecology [9]; 8) urban ecology approaches [10]; 9) urban political ecology approaches [11] and hybrids [12]. It is also notable that there is not yet a standardized framework.

Method

The first estimation of the urban metabolism of Ostersund city had an energy- and material flow approach. Three general methods were used to collect or produce data on material flows:

1) Local data was used as they were or recalculated to the population; 2) Regional data assumed to be representative also for the city of Östersund, often recalculated based on per capita or land use; 3) National data assumed to be representative also for the city of Östersund, often recalculated based on per capita or land use. A priority was given to local or regional data over national data.

First estimation

The results from our first estimation of some of the major material and energy flows in Östersund can be seen in Figure 1.

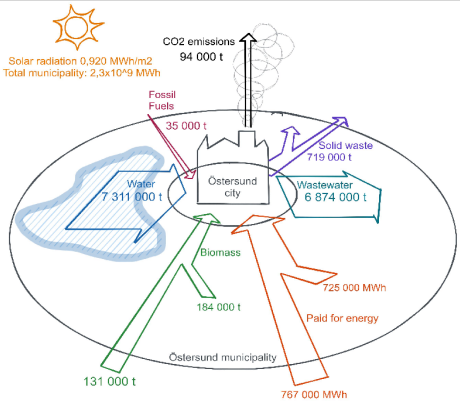

Figure 1. Annual major material flows (in tonnes) and energy flows (in MWh) used in Östersund city. A distinction is made between local production or treatment, and the import or export from and to outside of the municipality.

As can be seen from Figure 1, the flow of water is large compared to the other flows. Biomass and energy are both partially imported and partially produced locally to meet the rate of consumption.

Biomass

In Figure 2, local biomass production is specified. Most of the biomass weight produced comes from forestry while only a small part comes from agriculture. Within agriculture, most of the produced biomass is used to feed animals for meat, milk and eggs.

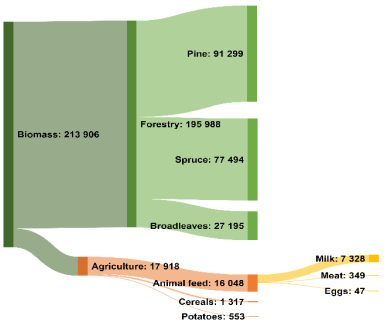

Figure 2. Yearly biomass production for consumption in the municipality of Östersund by industry and product, in tonnes

Energy

The distinction between the energy use in different sectors and different sources of energy is made in Figure 3. It shows how energy production in Östersund is dominated by renewable sources except when it comes to the transport sector.

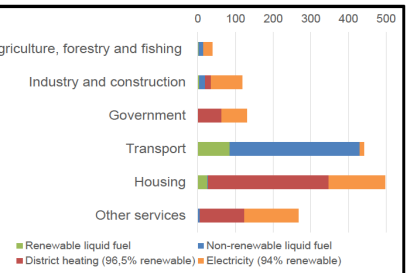

Figure 3. Energy use in the city of Östersund per sector and energy source in 2019, in GWh.

Discussion & conclusion

The material and energy flow analysis is a useful tool to better understand the major flows needed to maintain the city in its current state. This study starts to reveal the major flows of that type. The literature review shows that it can be used as the bigger picture, to which decisions in the different sectors of the city must relate, e.g. the impact of suggested circular flows, urban planning initiatives, or sustainable development policies and suggestions in general. Together, the large-scale assessment and the small-scale solutions can create a meaningful picture.

Assessing Stakeholder Engagement in Non-financial Reporting: Evidence from companies listed on the Italian stock exchange

Dr. Saverio Petruzzelli, Prof. Francesco Badia

University of Bari Aldo Moro, Bari, Italy

Abstract

Non-financial reporting is a fundamental aspect of the organizational learning process toward sustainability in the business context (Stolowy & Paugam, 2018). Among the necessary requirements for the realization of advanced practices of non-financial/sustainability reporting, there are stakeholder engagement and materiality analysis. Stakeholder engagement (Noland & Phillips, 2010) implies the process of involving an organization's stakeholders in understanding their interests and consequent information needs. Therefore, stakeholder engagement is recognized as a fundamental accountability and responsiveness mechanism, which implies the involvement of the subjects interested in the organization's activity, aimed at identifying and replying to their problems, expectations, and concerns, connected with sustainability. By performing effective stakeholder engagement, organizations can gather the necessary information to identify significant stakeholder issues, thus allowing a materiality analysis (Khan et al., 2016) of relevant information to be disclosed in sustainability reporting. The principle of materiality implies that the disclosure of non-financial information leads to highlighting those topics that have significant economic, environmental, and social impacts, or substantially influence stakeholder assessments and decisions. In this sense, materiality can represent a sort of beacon in the evaluation processes of sustainability strategies and their effectiveness (Whitehead, 2017). Stakeholder engagement and materiality analysis are strictly interconnected and find their theoretical reference in stakeholder theory (Freeman, 1994; Donaldson & Preston, 1995).

Starting from these premises, the purpose of this work is to investigate the quality of disclosure in the stakeholder engagement process. The research method utilized an assessment model based on 12 variables identified from an academic literature review and from the most common international sustainability reporting standards. Then, a specific system of indicators was identified for each variable. The disclosure quality assessment scores were obtained through the development of a content analysis (Krippendorff, 2018) on the non-financial statements published by companies listed on the Italian Stock Exchange.

The results reveal that during the stakeholder engagement process, the fundamental principle of inclusivity envisaged by stakeholder theory was not fully respected and observed. Moreover, the research shows lights and shadows regarding aspects such as reporting balance and impartiality, description of the impacts, and their corresponding influence on stakeholders, which appeared to be worthy of further investigation.

Supplementary information: Reference to SDG(s). Primary reference: SDG 12—Responsible consumption and production, Target 12.6; secondary references include SDG 8—Targets 8.5 and 8.8; SDG 12—Targets 12.2 and 12.5.

Relation to the conference topic. The connection of this work with the general conference theme lies in the research's attempt to highlight how sustainable development paths can be implemented by companies only in the presence of effective stakeholder engagement strategies and analysis of their effects on the system of stakeholder decisions. In this sense, the work seeks to promote a new "cultural" approach to the concept of sustainability in organizations based on the assessment of sustainability strategy effectiveness.

Assessing the Impact of Circular Strategies at the Company Level: Design and validation of the SCEIA framework (Strategic Circular Economy Impact Assessment)

Erik Roos Lindgreen[1], prof. Roberta Salomone[1], Prof. Tatiana Reyes[2]

[1]University of Messina, Messina, Italy. [2]UR INSYTE, Troyes, France

Abstract

Companies require assistance in assessing the sustainability of circular solutions prior to strategic decisions on their introduction. This article proposes and validates an ex-ante, holistic circular economy (CE) assessment framework SCEIA (Strategic Circular Economy Impact Assessment) at company level, using a mixed-methods approach. First, the framework's normative core and objectives are formulated. A critical literature review method is used to position this article's view that CE, as a concept, is valuable only when contributing positively to all three dimensions of SD. Secondly, a descriptive literature review of previously applied methods in CE assessment is used to design the framework's basic methodological structure, matching its previously defined normative core and objectives. The selected methods comprise a combination of the existing methods of Life Cycle Assessment (LCA), Life Cycle Costing (LCC), Social Life Cycle Assessment (S-LCA) and Material Flow Analysis (MFA). The number of resulting indicators can subsequently be tailored to the company's goals through a materiality assessment (MA). A Multi Criteria Decision Analysis (MCDA) TOPSIS approach is optional to assist in decision-making. Thirdly, the procedure of using the framework in a decision-making process at the strategic level is made explicit by connecting it to existing strategic decision-making frameworks and specifying its application routine. As a final step, the framework is validated through a dual triangulation process, consisting of an expert panel survey and online practitioner focus groups with companies. The expert panel consists of eleven CE assessment experts both from the academic realm as well as the private sector. Their input functions mainly as validation of the framework's objectives and methodological setup, while focus groups with eight companies provided insights into its practical feasibility. The triangulation process leads to various revised characteristics, which are reported on together with any potential contrasting inputs. The final SCEIA framework is designed to deliver valuable insights into the impacts of company-level CE activities. It has a modular structure and is applicable to companies with different levels of experience with assessment while preventing trade-offs and burden shifting.

Drivers and Barriers to Organizational Learning in Non-Governmental Organizations contributing to the Sustainable Development Goals

Ms. Gillian Martin Mehers

Radboud University, Nijmegen, Netherlands

Abstract

Non-governmental organizations (NGOs) are important social actors and recognized for their diverse contributions as a sector to social development and to the Sustainable Development Goals (SDGs). They are, however, challenging to understand as a phenomenon. It is often problematic to refer to them in aggregate, as they are an extremely diverse set of organizations, and as such, hard to generalize, making the 'NGO' complex to study. Indeed, they are often categorized by what they are not – not government, nor business.

NGOs need to navigate an increasingly complex, dynamic and often unpredictable environment to survive and to achieve their social goals. This changing environment has prompted for many NGOs a move into new territory in terms of strategy, management practice, and organizational structures, as they shift towards hybridization and social enterprise models in search of their own sustainability. Organizational learning is connected in academic literature to improved performance and competitiveness, as well as adaptation to change. In spite of the (near) agreement of authors of the benefits of organizational learning for NGOs, there has been relatively little empirical research on the processes that could drive the adoption and effective use of organizational learning to help NGOs adapt to changes outside their organization and strengthen their outcomes.

This research paper aims to elucidate the drivers and barriers to organizational learning for NGOs in the sustainability sphere. To do so, both the drivers and barriers for organizational learning are analyzed. Then, a conceptual framework for understanding organizational learning in NGOs is presented. Building on a survey of NGOs and their external and internal stakeholders which yielded 206 responses from 155 unique organizations, factor analysis brings to the fore four key attributes that help explain outcomes: leadership, culture, capacity, and structure. Among these, the data suggest the latter two play the greater role in whether or not an NGO is perceived to be a learning organization. Finally, implications of these findings for facilitating organizational learning in NGOs are discussed.

The Pareto Checklist for Sustainable Development

Mr Max Rosvall

Quality science, Visby, Sweden

Abstract

A sustainable development is the main concept capturing the grand process of achieving a good life for all while remaining a healthy planet. Since the early definition of the concept in Stockholm 1972 at the United Nations Conference on the Human Environment (UNCHE), it has always had the well-being of people in focus. With the inclusion of the future generations of people, the planet becomes the second main focus for sustainable development. However, with the increasing pressure from consumers and civil society the notion of sustainability has become a safe-haven for decision makers due to the ambiguity of the concept. Without any universal definition of the state of sustainability, the creation of narratives that goes ahead and harden the inherently unsustainable status-quo prompting for business as usual is of course present. In challenging this narrative, we can draw support from the scholarly field of quality applying a pragmatic approach with a focus on processes and fact-based decision making.

Building on the matrix Sustainability Opportunity Study (SOS), this paper complements previous research in guiding the identification and selection of key stakeholders and impacts for sustainable development. This is done with a focus on processes and applying a fact-based decision-making model. The pareto principle is used to filter out the few vital impacts and going beyond previous research by Isaksson et al (2015) a checklist with vital threats and opportunities for sustainable development is derived from frameworks like Planetary Boundaries, Agenda 2030 and the system principles from the framework for strategic sustainable development. We will focus people and planet to derive key stakeholders for which a needs-based approach is used to map out key sustainability impacts. The iterative nature of the SOS study calls for the framework to provide a second, third and Nth set of key performance indicators for sustainable development. This is not done in previous research, and remains as a challenge for future work.

Triple Loop Learning in Environmental Management Practice: Evidence of the RedES-CAR dissemination program

Ms. Silvia Correal, Dr Bernardas Van Hoof, Msc Joan Salcedo

Universidad de los Andes, Bogota, Colombia

Abstract

Environmental management practice includes the processes related to the organizational changes meant to improve the environmental performance of a firm. Advanced levels of organizational learning involve cultural changes, also identified as triple loop learning. The purpose of this research is to evaluate the outcomes and conditions of triple loop organizational learning process occurring in companies that participated in a cleaner production dissemination program in Colombia. Literature on triple loop learning in environmental management practices provided a framework of analysis. Mixed research methods included regression analysis and empirical data comes from the RedES-CAR program, including 500 firms of which 45 identified triple loop learning and interviews with project leaders of firms evidencing triple loop learning in cleaner production implementation. Outcomes operationalize triple loop learning through newly develop cleaner production practices. Conditions on TLL, include information exchanges among participants and leadership of decision makers. This research adds to literature by using empirical data of how companies advance triple loop learning in the cleaner production practice. In addition, it determines factors supporting triple loop organizational learning in environmental management. Moreover, it further provides recommendations for managers involved in environmental management practice in firms and provide guidance for the design and development of dissemination programs aiming at cultural changes in firms.

Using Meadows' Leverage Points as a Tool to Assess Effective Sustainability Impacts

Dr Giulia Sonetti

CENSE, Lisbon, Portugal

Abstract

The environmental crisis, in its current and dramatic global extension, may perhaps be the decisive stimulus for a radical transformation of sustainability science. To be able to carry out an ecological and cultural revolution, a new, impact-focused approach must then be transdisciplinary and transformative, through the assumption of individual and collective responsibility, a long-term scenario and socio-political empowerment.

But what does it mean to have an impact and provoke a systemic shift?

The aim of this research is to test meadows' leverage points theory as a tool to assess the efficacy and the impacts of transformative interventions described in the sustainability active research literature. We first tailored the implementation of every leverage points in accordance with our field of study; then, we made a search on Scopus and Web of Science databases to code the results via an algorithm in Python to select and cluster a final corpus of 77 papers suitable for our scope. Finally, we ranked those items looking at the outcomes of academic practices and their shallow/deep leverage potential in a Sankey diagram, to understand which factors really affected the success of the sustainability project. Most of the examples related to what Meadow considered "deep leverage points", i.e. leading to a systemic change of rules, assessment methods, and goals of an institution. Results show that interventions declare ambitious aims just added something new to stable systems, not hindering the system itself if not accompanied by a follow-up and tangible actions. Conclusions highlights that though many projects are aimed to touch deep leverage points for a complete paradigm shift of education, the collaboration between institutions and external stakeholders must be improved. Furthermore, teachers and researchers designing an intervention must reflect on how to create also a bottom-up perspective, changing the role and the relation between teachers and students and non-academic actors in transformative learning processes. Research also suggests paying attention to clear communication of results, quantitative and/or qualitative should they be, for an effective successful sustainability process.

Abstract

The maritime sector is considered one of the most important contributors to the international and European economy. The European Commission highlighted that among the identified seven sectors that include all the main blue economy activities, maritime transport, the activities of the port, and shipbuilding and repair contributed about 40% to the total added value of the blue economy, in 2019. In addition, although shipping is currently deemed the most low-carbon way of cargo transportation, its environmental impacts increased during the last years, requiring additional improvements oriented to increase its performance. This is particularly true when the whole life cycle of a maritime means of transport is considered, including design, shipbuilding, operation, maintenance, and end of life. The Life Cycle Assessment (LCA) method has been widely adopted for assessing the environmental charges related to the maritime sector, particularly focusing on the assessment of ships. Despite this, few studies have been performed for evaluating the maintenance and repair activities. Besides, among the international scientific literature, there is a lack of inventory data specifically focused on ship maintenance. In this context, the study here presented aims to assess the potential environmental impacts connected to the maintenance activities of a Roll-on/Roll-off (Ro-Ro) ferry, through the application of the LCA method, by first analysing the maintenance processes as an overall, considering the amount of steel used in the hull and superstructure carpentry and the electricity consumed (System A), then, by specifically focusing on the hull maintenance and related processes (System B). In addition, the study provides a dedicated inventory related to such maintenance activities. Two functional units were defined to satisfy the aim of the study, in particular, "the extraordinary maintenance of the Ro-Ro ferry implemented during 47 days" for System A, and "the replacement of the damaged hull structures during the Ro-Ro ferry maintenance carried out in 47 days, resulting in 3.28 m^2 replaced surface" for System B. System boundaries were defined for both the systems by following a "cradle to gate" approach. Foreground data were collected through a shipping company operating in Italy, while background data were obtained using dedicated databases. The main results highlight that for both the systems under consideration the input of steel is responsible for the highest environmental impacts. For example, the 450.75 kg of steel used to replace 3.28 m^2 of damaged hull surface accounts for 1,364.17 kg

System B, the higher environmental impacts are caused by the welding and painting activities. The results also allow pointing out the need for alternative materials as substitutes for the steel used in shipbuilding as well as the necessity of analysing the maintenance phase in addition to the operation one when different means of transport are compared.

Keywords: ferry, cargo ship, Life Cycle Assessment (LCA), environmental impact, maintenance

1 Introduction

Nowadays, the maritime sector represents the core of the international economy being involved in 80% and 70% of the international trade, respectively, by volume and by value (UNCTAD, 2018). Focusing on the European context, among the main blue economy activities identified by the European Commission, maritime transport and related systems and services contributed 40% to the total added value of the blue economy in 2019 (European Commission, 2021). Despite maritime transport being considered the *most carbon-efficient mode of transportation*, with particular reference to cargo transport (European Commission, 2021), its related greenhouse gas (GHG) emissions increased from 977 to 1,076 million tonnes, between 2012 and 2018 (IMO, 2020). Thus, actions oriented at reducing and monitoring the environmental impacts caused by the transport sector are required. In this context, the Life Cycle Assessment (LCA) may be considered a robust and valid method for evaluating the environmental consequences of maritime transportation as well as for identifying strategies oriented at improving its environmental performance. According to Mondello et al. (2021), LCA has been widely adopted in this regard, specifically focusing on the assessment of the life cycle phases of maritime means of transport, i.e., shipbuilding, operation, maintenance, and end of life. The international scientific literature shows that most of the LCA studies specifically focus on the assessment of the operation phase (Mondello et al., 2021) by comparing, for example, different types of marine fuels (e.g., Perčić et al., 2020). On the contrary, few LCA studies focus on the assessment of the environmental impacts associated with maintenance activities. For instance, Wang et al. (2018) analysed the environmental and economic impacts of a ship hull specifically focusing on steel maintenance and coating in order to identify an optimal hull maintenance strategy. Furthermore, due to the huge amount of information and data related to ship maintenance activities, the LCA method is commonly applied by mainly using data obtained through formulas, estimations, and literature, instead of primary data for which the collection may be demanding. Besides, ship maintenance can be considered, on the one hand, a fundamental activity in maritime transport, ensuring travel security, efficiency and cost reduction and, on the other, an activity requiring remarkable amounts of materials and energy sources which may result in high environmental impacts.

In this context, this study aims to evaluate the potential environmental impacts connected to the maintenance activities of a Roll-on/Roll-off (Ro-Ro) ferry, operating in Italy, by implementing the LCA method. In particular, two different hot-spot analyses are performed. First, an evaluation of the environmental performance associated with the materials and energy sources, in terms of steel used for the carpentry of hull and superstructure, and electricity consumed during the whole maintenance activity, is carried out (System A). The choice of only assessing, as material, the steel focusing on carpentry, and thus

cargo ship. Then, the specific assessment of the hull maintenance is carried out by considering the amount of steel as input and all the related processes (e.g., cutting, welding, painting, etc.). Consequently, a Life Cycle Inventory (LCI) mainly based on primary and measured data related to the investigated Ro-Ro ferry maintenance activities is also provided.

2 Methods

In this section, first, the characteristics of the investigated ship are reported, and then the LCA method and related data used for carrying out the study are described.

2.1. The investigated Ro-Ro ferry

Table 1 reports the main characteristics of the naval unit under investigation, which is represented by a Ro-Ro ferry, operating in Italy, used for the maritime transportation of wheeled vehicles (i.e., trucks) and passengers. In contrast with the Lift-on/Lift-off type, in the Ro-Ro ships, the vehicles are loaded and uploaded by rolling instead of being moved by cranes (Kim et al., 2007).

Table 1. *Main characteristics of the investigated ship.*

Type	Roll-on/Roll-off; passenger
Passengers (max)	300
Load	340 m
Length	97 m
Engine	4x MAN D2842LE408 736 kW
Propeller	4 x Aquamaster Azimut Propeller
Hull surface	1527 m^2
Operation place	Italy
Maintenance place	Italy

Ferries are constantly subjected to maintenance activities including the refurbishment/restoration or substitution of the ship components as well as carpentry, washing, and painting processes. The investigated ferry is subjected to two different kinds of maintenance activities: a) ordinary, which occurs every month and is commonly performed without suspending the transport services, and b) extraordinary, which is carried out every two years, mainly on dry-dock. The extraordinary activity implies the inspection and maintenance of all the ship: i) engines and propellers, ii) outfitting, iii) valves, pumps, and pipes, iv) structures (i.e., hull, and superstructure).

2.2. The Life Cycle Assessment method

In order to satisfy the aim of the study here presented, the environmental performance of the analysed ship maintenance activities has been evaluated by implementing the LCA method. LCA is a standardised method that allows assessing the potential environmental impacts of a product, process, or service throughout its whole life cycle, from raw material extraction, through manufacturing, transport, use and final disposal (ISO, 2006a; ISO, 2006b). This method is characterized by four iterative phases, i.e., goal and scope definition, life cycle inventory

2.2.1. Goal and scope definition

LCA method was applied to assess the environmental performance related to an extraordinary maintenance activity of a Ro-Ro ferry by analysing two different systems. First, the assessment was focused on the amount of steel installed and removed during the carpentry activities carried out on the ferry structures (i.e., hull and superstructure) as well as on the electricity consumption for the whole maintenance process (System A). Then, the hull maintenance has been specifically analysed focusing on the processes involving the substitution of steel structures and the painting (System B).

Two different functional units (FUs) have been identified for both the investigated systems, respectively considering: i) "the extraordinary maintenance of the Ro-Ro ferry implemented during 47 days**"** for System A, and ii) "the replacement of the damaged hull structures during the Ro-Ro ferry maintenance carried out in 47 days, resulting in 3.28 m^2 replaced surface" for System B. System boundaries were defined following a "cradle-to-gate" approach, thus from the acquisition and production of raw materials and energy sources to the time in which the maintenance activities are completed and the ship is ready to be launched. In particular, for System A the system boundaries include the electricity used during the whole maintenance, from dry-dock to the launch of the ship, as well as the steel used to repair the damaged ship structures, considering both the hull and the superstructure. Whereas, for System B the system boundaries refer to all the carpentry and painting processes implemented during the hull maintenance, i.e., cutting, beveling, welding, washing, and spray painting as well as to the related inputs (e.g., steel, water, paint, etc.). System boundaries for both systems are graphically represented in Figure 1.

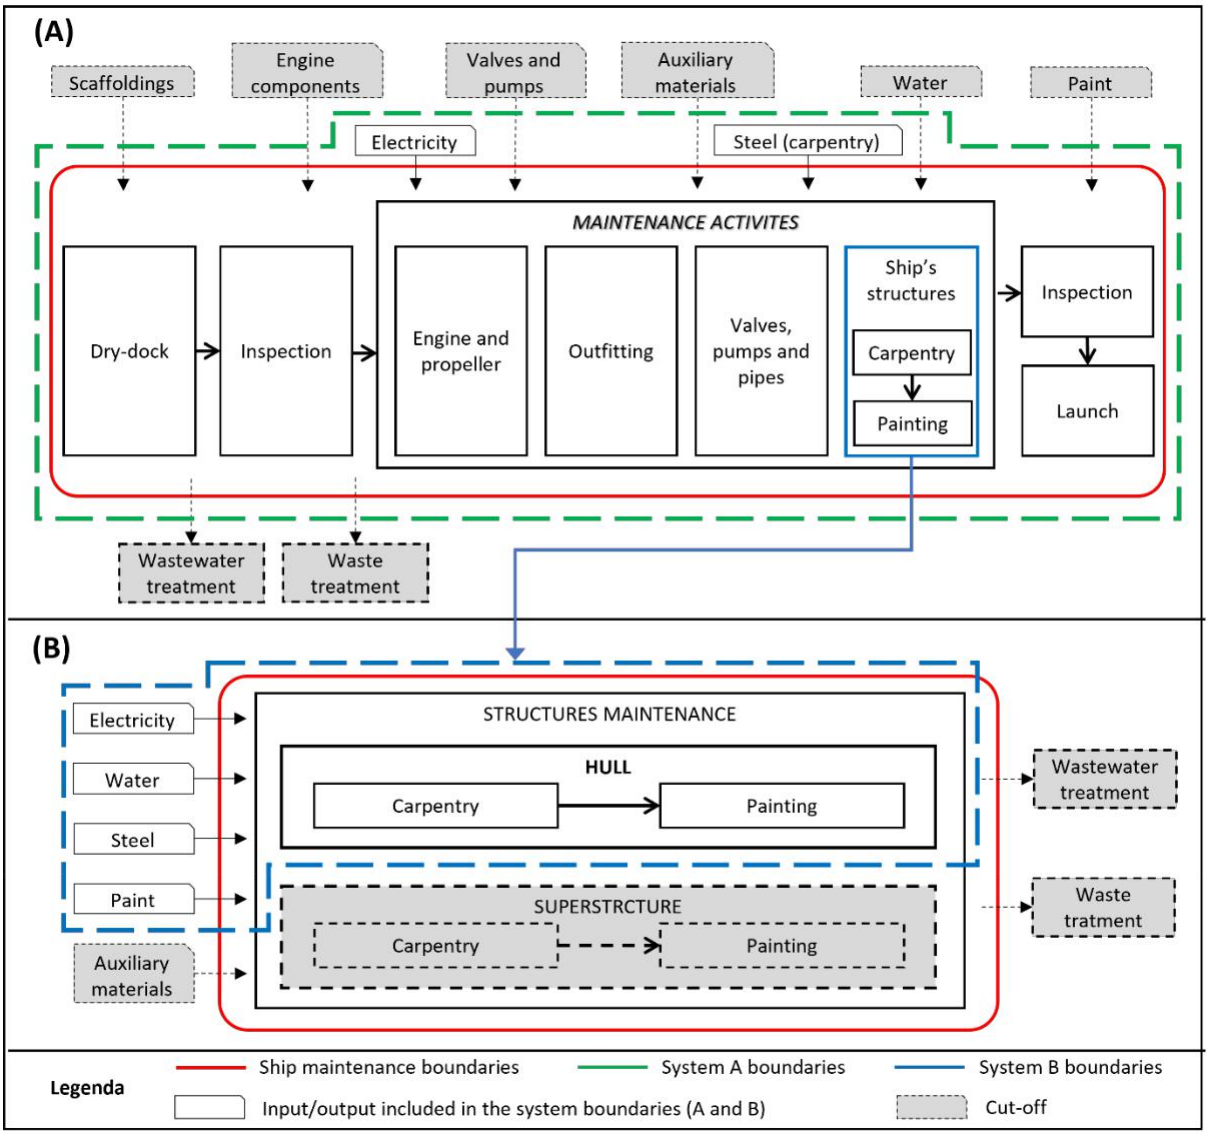

***Figure 1**. Analysed system boundaries for System A and System B.*

Cut-off criteria were defined by excluding processes and related input and output for which the assessment was not necessary because outside the scope of the present study (e.g., engine components, water, etc.), while, other processes were omitted due to the lack of specific information and inventory data (e.g., auxiliary materials in System B). Furthermore, infrastructures were also omitted from the analysis.

2.2.2. Life Cycle Inventory

The LCI phase has been carried out by using both primary and secondary data. In particular, primary data were obtained through questionnaires and direct interviews submitted to the company owner of the investigated Ro-Ro ferry. On the contrary, secondary data were gathered by dedicated databases (Ecoinvent 3.8 – Moreno Ruiz et al., 2021). Table 2 shows the main inventory data used for analysing the investigated systems, while table 3 reports the description and characteristics of the different processes implemented during the hull maintenance in System B. As reported above, for System A, only the amount of steel used for carpentry has been considered, while for System B, the processes of steel production and sheet modelling were accounted in addition to the amount of steel as an input.

System	Input/Output/Process	Unit	Amount	Data Source
A	Steel (carpentry)	kg	1,659.39	Measured data; Ecoinvent 3.8
	Electricity	kWh	2,774.00	Measured data; Ecoinvent 3.8
B	Steel (raw)	kg	450.75	Measured data; Ecoinvent 3.8
	Steel sheet (modelled)[a]	kg	405.68	Measured data; Ecoinvent 3.8
	Cutting	m	8.20	Measured data; Ecoinvent 3.8
	Beveling (electricity)	kWh	16.40	Calculated data; Ecoinvent 3.8
	Welding	m	43.80	Measured data; Ecoinvent 3.8
	Washing (water)	L	450.00	Calculated data; Ecoinvent 3.8
	Washing (electricity)	kWh	17.50	Calculated data; Ecoinvent 3.8
	Painting	m^2	6.56	Measured data; Ecoinvent 3.8

[a]10% of the raw steel (45.7 kg) is loss (as scrap) during sheet modelling (company communication).

Further information reporting the description and characteristics of the different processes implemented during the hull maintenance in System B are shown in table 3.

Table 3. *Activities carried out for hull maintenance in System B.*

Process	Description	Material/Equipment	Hull surface treated per hour[1,2,3]	Number of operators
Cutting	Removal of the damaged steel sheet from the hull	Oxy-fuel (oxyacetylene gas) cutting	10 m/h	1
Beveling	Edge refinement of the cut surface in order to make it ready for the subsequent welding	Angle grinder	1 m/h	1
Welding	Positioning of the new steel sheet and related welding to the hull	Metal wire/Gas Metal Arc Welding (GMAW) – MIG/MAG (ISO, 2019)	5 m/h	1
Washing	Cleaning of the repaired surface in order to remove impurities	Water/Industrial pressure washer	25.4 m^2/h	4
Painting	Coating the new steel sheet with two layers of painting in order to provide anticorrosive and antifouling protection	Antifouling silicone paint / airless spraying pump	509 m^2/h	4

[1]Direct communication by the company; [2]Amounts related to a steel sheet of 14 mm thickness; [3]The reported amounts are related to the number of operators carrying out the maintenance activity.

2.2.3. Life Cycle Impact Assessment

The potential environmental impacts related to the systems under consideration (System A and System were assessed by using SimaPro 9.3 software (PRé Sustainability, 2021) by applying the CML-IA baseline 3.07 method which includes ten different impact categories, specifically, abiotic depletion, abiotic depletion (fossil fuels), global warming (GWP100a), ozone layer depletion, human toxicity, freshwater aquatic ecotoxicity, marine aquatic ecotoxicity, terrestrial ecotoxicity, photochemical oxidation, acidification, and eutrophication. This method was selected because, on the one hand, it includes the most relevant impact categories to be considered for maritime context (Ling-Chin and Roskilly, 2016), on the other, it allows

3. Results and Discussion

In this section, first, an overview of the results related to System A is reported, and then a detailed analysis of the environmental impacts caused by System B and the related processes is provided.

3.1. System A

Figure 2 shows the contribution analysis related to System A, per each of the selected impact categories. The results highlight that the steel used for carpentry in System A causes the highest potential environmental impacts in all the investigated impact categories. Indeed, its percentage contribution ranges from 97.9% (6,024.48 kg 1,4-DB eq per FU) in freshwater aquatic ecotoxicity to 50.9% (1.25E-04 kg CFC-11 eq per FU) in ozone layer depletion. The high environmental impacts caused by steel are due to the production process for which secondary data from Ecoinvent 3.8 database were used. Regarding electricity, the results show that the main impacts (where percentage contribution is higher than 30%) are related to ozone layer depletion, abiotic depletion, acidification, and terrestrial ecotoxicity. Depending on the impact category considered the contribution of electricity depends on its production or distribution. For example, for ozone layer depletion the highest impacts are connected to the transport of natural gas through onshore pipelines.

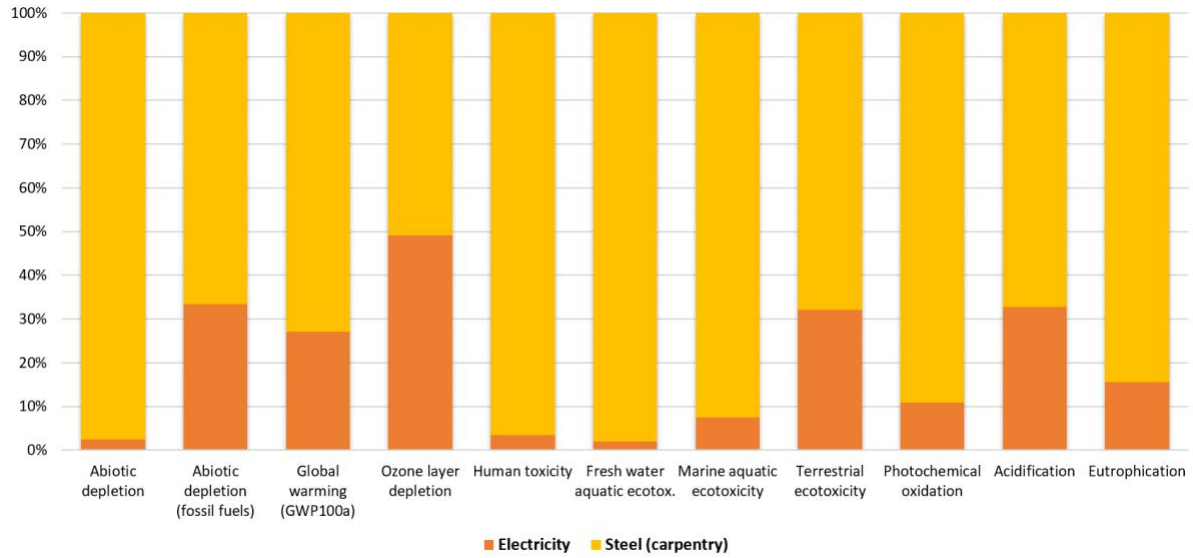

***Figure 2**. Contribution analysis of System A (CML-IA baseline – characterisation).*

The results here presented also point out the higher weight in terms of contribution to the environmental impacts connected to the use of steel in the Ro-Ro ferry. Indeed, despite the amount of steel considered in System A is only related to the carpentry activities, thus excluding the steel used in other maintenance processes (e.g., pipes, outfitting, etc.), it causes the highest contribution to the impacts when compared to the electricity consumption, for which data are representative for the whole ship maintenance.

3.2. System B

The overall assessment of the environmental impacts related to System B is reported in table 4. Focusing on global warming (GWP100a), which represents the most important impact category to be evaluated in maritime transport (Czermański et al., 2020), the hull maintenance of the investigated Ro-Ro ferry causes 1,364.18 kg of CO_2 eq per FU. Considering that maritime transport represents the most environmentally friendly mode of cargo transportation in terms of GHG emissions (European Commission, 2021), the results here presented underscore the need of analysing all the life cycle phases, including also the maintenance, when diverse means of transport are compared, instead of only evaluating the operation phase (e.g., fuel consumption, emission due to wear, etc.). This is particularly true considering that, on the one hand, the extraordinary and ordinary maintenance activities can extremely vary between different means of transport (e.g., truck, train, ship, and aircraft), on the other, those activities occur many times during vehicle lifetime.

Table 4. *Potential environmental impacts of System B* (CML-IA baseline – characterisation)

Impact category	**Unit**	**Total**
Abiotic depletion	kg Sb eq	2.13E-03
Abiotic depletion (fossil fuels)	MJ	14,312.88
Global warming (GWP100a)	kg CO_2 eq	1,364.18
Ozone layer depletion	kg CFC-11 eq	8.53E-05
Human toxicity	kg 1,4-DB eq	1,587.85
Freshwater aquatic ecotoxicity	kg 1,4-DB eq	3,537.47
Marine aquatic ecotoxicity	kg 1,4-DB eq	1.02E+07
Terrestrial ecotoxicity	kg 1,4-DB eq	1.40
Photochemical oxidation	kg C_2H_4 eq	0.55
Acidification	kg SO_2 eq	4.03
Eutrophication	kg PO_4^{---} eq	2.65

Figure 3 reports the percentage contribution of the processes implemented in hull maintenance as well as of the steel production and sheet modelling. The identified findings are in line with the ones obtained for System A, indeed, also in System B, the impacts associated with steel production and modelling contribute more than 90% to all the analysed impact categories (e.g., 1,364.17 kg CO_2 eq per FU in terms of global warming). Furthermore, the highest environmental impacts due to steel production and modelling are related to maritime aquatic and freshwater aquatic ecotoxicity, contributing 99.6% and 99.5% to the overall environmental impacts, respectively.

***Figure 3**. Contribution analysis of System B (CML-IA baseline – characterisation).*

An in-depth analysis highlights that the higher impact of sheet modelling caused in maritime aquatic ecotoxicity (table 5) is due to the electricity and heat used during the metalworking process. On the contrary, steel production results in higher impacts for photochemical oxidation, human toxicity, and global warming impact categories. This higher contribution, in comparison to the sheet modelling, is caused by the blast furnace process and, in particular, by the liquefied pig iron used in steel production.

***Table 5.** Potential environmental impacts of steel production and sheet modelling in System B (CML-IA baseline – characterisation).*

Impact category	Unit	Steel production	Sheet modelling	Total
Abiotic depletion	kg Sb eq	1.88E-04	1.88E-03	2.07E-03
Abiotic depletion (fossil fuels)	MJ	6,978.98	6,854.15	13,833.13
Global warming (GWP100a)	kg CO_2 eq	713.61	616.03	1,329.64
Ozone layer depletion	kg CFC-11 eq	3.39E-05	4.71E-05	8,10E-05
Human toxicity	kg 1,4-DB eq	985.11	562.28	1,547.39
Freshwater aquatic ecotoxicity	kg 1,4-DB eq	1,636.47	1,882.19	3,518.66
Marine aquatic ecotoxicity	kg 1,4-DB eq	1.98E+06	8.14E+06	1.01E+07
Terrestrial ecotoxicity	kg 1,4-DB eq	0.26	1.14	1.40
Photochemical oxidation	kg C_2H_4 eq	0.40	0.15	0.55
Acidification	kg SO_2 eq	2.08	1.95	4.03
Eutrophication	kg PO_4^{---} eq	1.37	1.28	2.65

Regarding the different processes involved in hull maintenance, figure 4 and table 6 respectively show the results in terms of contribution analysis and environmental impacts (absolute values). In particular, welding and painting represent the processes causing the main contribution to the impacts, instead washing is responsible for the lower environmental charges.

***Figure 4**. Contribution to the environmental impacts of the processes investigated in System B (CML-IA baseline – characterisation).*

From the analysis of each process emerges that the highest environmental impacts related to welding activities are identified in abiotic depletion, human toxicity, terrestrial ecotoxicity, and fresh water and marine aquatic ecotoxicity, for which the percentage contribution to the overall impacts ranges from 96% to 49.1%. Specifically, the higher impacts related to these categories are due to the steel wire used to weld the new sheet to the hull. Besides, the main impacts attributed to the painting process, in ozone layer depletion abiotic depletion (fossil fuels), and global warming, are due to the electricity consumed by the airless spraying pump. As for the painting, electricity use is also the major contributor to impacts caused by the beveling process. Lastly, both cutting and washing are the activities to which the lower environmental impacts are connected, contributing to less than 10.6% in all the impact categories analyses.

Table 6. *Potential environmental impacts of the maintenance processes in System B (CML-IA baseline – characterisation).*

Impact category	Unit	Cutting	Beveling	Welding	Washing	Painting	Total
Abiotic depletion	kg Sb eq	2.25E-08	1.08E-07	5.24E-05	3.04E-08	2.04E-06	5.46E-05
Abiotic depletion (fossil fuels)	MJ	3.13	76.28	72.68	21.01	306.64	479.75
Global warming (GWP100a)	kg CO_2 eq	0.54	5.80	6.85	1.60	19.75	34.54
Ozone layer depletion	kg CFC-11 eq	1.20E-08	7.10E-07	3.25E-07	1.96E-07	3.08E-06	4.32E-06
Human toxicity	kg 1,4-DB eq	4.28	0.77	29.97	0.22	5.22	40.46
Freshwater aquatic ecotoxicity	kg 1,4-DB eq	0.21	0.75	13.17	0.21	4.46	18.81
Marine aquatic ecotoxicity	kg 1,4-DB eq	8.54E+02	3.51E+03	1.96E+04	9.72E+02	1.47E+04	3.96E+04
Terrestrial ecotoxicity	kg 1,4-DB eq	0.01	2.71E-03	0.08	7.49E-04	0.01	0.11
Photochemical oxidation	kg C_2H_4 eq	2.31E-04	1.08E-03	2.65E-03	2.97E-04	3.64E-03	0.01
Acidification	kg SO_2 eq	1.26E-03	0.02	0.03	0.01	0.06	0.12
Eutrophication	kg PO_4^{---} eq	9.51E-04	0.01	0.02	1.76E-03	0.02	0.05

4 Conclusions

This study aimed to analyse the potential environmental impacts of the maintenance activities of a Ro-Ro ferry, operating in Italy, through the LCA method. Two different systems were investigated to obtain the environmental profile related to the materials and energy sources respectively used during the ship maintenance as a whole (System A) and the specific maintenance of the hull (System B). For System A the analysis was focused on the total amount of electricity consumed during the whole maintenance of the ship, as well as on the steel used for carpentry activity carried out in the steel structures of the ship (i.e., hull and superstructure). For System B the analysis was performed by considering the amount of steel in input, the steel sheet modelling and all the processes implemented during the hull maintenance (e.g., cutting, welding, painting, etc.).

The main findings from the analysis allowed highlighting that the higher contribution in all the selected impact categories was related to the steel used to repair the damaged ship structures, in both the investigated systems. This result is in line with Garfield (2018) who highlighted the higher impacts connected to steel structures and, in this regard, the increasing need for more environmentally friendly materials (e.g., fibre-reinforced polymers) in cargo shipbuilding, specifically for the construction of the hull and the superstructure. Focusing on System B, the results underscored that the impact in terms of global warming caused by the maintenance of 3.28 m^2 hull surface (representing only 0.2% of the whole surface of the investigated Ro-Ro ferry) was equal to 1,364.18 kg of CO_2 eq. In this context, despite shipping being considered the most carbon-efficient mode for cargo transportation, its comparison to other means of transport (e.g., truck, train, etc.) should not only be limited to the operation phase but it should be performed by analysing all the life cycle phases, thus also including the maintenance activities that, as resulted from this study, are responsible for high environmental impacts.

Regarding the processes investigated in System B, the main contribution to the impacts was connected to the use of steel wire for the welding activities, as well as to the electricity consumed by the equipment used for the painting process.

Lastly, considering the lack of dedicated inventory data to be used for assessing the maintenance activities or maritime means of transport, the present study allowed to provide useful data mainly gathered from primary sources that may be useful for researchers and ship-owners who want to perform a similar analysis.

Future research should be oriented toward assessing the whole maintenance activities of a cargo ship by also including the amount and type of materials used to repair the engines, outfitting and other ship components. This would allow obtaining a complete picture of the environmental performance related to the whole activities that occur during the maintenance of a cargo ship. In addition, the life cycle thinking approach should be adopted to analyse all the costs related to ship maintenance activities including the costs related to externalities. In this context, the application of the Life Cycle Costing method would further help ship-owners in decision-making processes.

Sustainability as Societal Value & Cultural Fact: A framework for value accounting

Swaminathan Ramanathan[1]

[1]*Uppsala University, swaminathan.ramanathan@angstrom.uu.se*

Abstract

The World Economic Forum (WEF) & the International Business Council (IBC) in its key 2020 whitepaper on Measuring Stakeholder Capitalism put forward two concepts of Value Accounting and Dynamic Materiality. According to WEF, these two concepts are the foundation of a new 'form of capitalism' where a stakeholder is conceived to be as important as the owner. In the longer run, these concepts are expected to augment and potentially replace the two existing and well-established concepts of Revenue Accounting and Materiality. Revenue Accounting in simple terms is Profit & Loss (P&L) and Return of Investment (ROI) that is aggregated in the form a balance sheet: the main documentary evidence of formal financial reporting. It is the basic building block of all business models. Materiality is an accounting concept used for financial reporting. Materiality for sustainability reporting derives its inspiration from the same concept and is today largely operationalised through GRI's 'cradle-to-grave' materiality framework and the resultant Scope 1, 2, & 3 emissions accounting. Organisations have traditionally struggled with comprehensively measuring Scope 2 & 3 emissions, with Scope 3 emissions constituting as much as 98% of the emissions of many large companies that are tightly coupled to global supply chains. Sustainability materiality assessment has always been a challenge for companies. Now, with rapid climate change bringing to the fore the fact that sustainability reporting and assessment in its current form is neither sufficient nor adequate to help combat global warming, the spotlight is firmly on companies to stop 'greenwashing' their environmental, social and governance (ESG) footprints. WEF's Stakeholder Capitalism and its two pillars of Dynamic Materiality and Value Accounting can be considered a response to the criticism of 'greenwashing', yet they are also a further challenge to the already struggling companies to understand, define and measure their ESG footprint as per the concepts of Dynamic Materiality and Value Accounting. The authors explore three conceptual themes. The first is the theme of 'Stake' in Stakeholder Capitalism. For stake to be understood and defined in any practical manner for companies, there is need for an overarching assessment framework. The second is the theme of value. For value to be accounted for in the same or least equivalent manner as revenue it needs to be quantified in a manner that makes it comparable to revenue. In short, value needs a common foundation for understanding, defining, and measuring it. The third is the theme of materiality. For materiality to be conceived as a dynamic entity, there is scope to look at metrics and measures as part of a processes rather as an output or an outcome. The authors will engage in an initial manner with the Process Based System Model (PBSM) to lay out a case that sustainability can be conceived as a set of inputs, processes, and outputs. In conclusion, the authors argue that a Value Accounting framework will need to be deeply anchored to societal values and cultural foundations for sustainability to genuinely become part of daily life.

1. Introduction

Theoretically and conceptually, we do not have a common understanding and definition of sustainability. By extension, there is a lack of a common measurement framework of and for sustainability. As a result, sustainability can appear to be clear or blurred depending on one's domain, the key disciplinary boundaries, and its vantage points. Within the domain of social sciences an anthropologist, for example, may as a matter of theoretical approach and methodological training approach any issue of sustainability as one of practices of daily life of people and communities. Similarly, within the domain of natural sciences an evolutionary biologist, for instance, may approach sustainability as a key issue of microenvironments, biodiversity protection and ecological carrying capacity. There is no shared bridge for an anthropologist and an evolutionary biologist to come closer and evolve a comprehensive understanding and definition of sustainability. In such an environment sustainability quickly becomes a contested term, with sustainability being defined either in very broad terms of a worldview requiring a radical transformation or within an extremely narrow spectrum of solutions requiring a series of incremental transitions.

The one potentially useful way to approach sustainability in such contested environments is to functionally define it for a limited purpose of treating it as starting point for an enquiry into the key question of a practical understanding of sustainability for key user groups. Our paper uses this approach for the key user group of companies. From the vantage point of today, as a here and now moment, it is easy to agree that we are not sustainable globally. We currently use yearly the production of about 1.8 planets to satisfy our needs; with Sweden requiring as much as 4.3 planets to sustain its quality of life (Living Planet Report, 2022). We have crossed several planetary boundaries in areas such as climate change, novel entities, and loss of biodiversity (Steffen et. al., 2015; Persson et. al., 2022). The only way for us to understand, define and measure sustainability in a practical manner is to understand, define and measure unsustainability of today. In short, sustainability can only be understood as a bipolar opposite of unsustainability; or as a new equilibrium state for an existing system-of-systems (Snowden and Boone 2007; IBM, 2011) whose current state of equilibrium is misaligned with the required equilibrium of the Earth system (Steffan, Rockström, Richardson et. al. 2018).

Within this definitional context, there are three key developments that need to be highlighted. The first is connected directly to the future of Sweden. On April 7, 2022, Sweden became the first country in the world to commit to a Consumption-Based Emissions target (Sveriges globala klimatavtryck, 2022). Sweden's decision represents a concrete challenge and clear opportunity to researchers for evolving an integrated framework for measuring sustainability that simplifies reporting for companies and institutions. Currently about 60% of Sweden's emissions are released in countries that produce goods and services consumed in Sweden (ibid). Such emissions are not accounted for as part of Sweden's climate impact since carbon calculations are based on territorial-based or production-based emissions accounting

based emissions accounting framework (Lenk et. al. 2021; Bhattacharya, et. al. 2020) or a global shift to a consumption-based emissions accounting framework (Chen, et. al.

2018). There is also emerging work that is recommending emissions pathways to be framed within the boundaries of a "climate-social system" (Moore, et. al., 2022). Sweden's decision to adopt a consumption emissions target inclusive of the climate impact of its exports, emissions from flights and cargo ships comes in the immediate context of humanity's unsustainability: a fundamental disequilibrium of the anthropogenic system.

The second is connected to the state of the planet. The IPCC AR6 report released on April 4, 2022 clearly points out that limiting global warming to around 1.5° C of the pre-industrial levels as agreed and ratified by countries who signed the Paris Agreement requires not only the Greenhouse Gases (GHG) emissions to peak before 2025, but also to be reduced by 43% by 2030. Additionally, the report warns of a methane gas reduction by a third in the same period (IPCC, 2022). The primary sources of Carbon, GHG and methane gas are human [anthropogenic] activities, which largely are the result of an 'input-throughout-output' value creation processes of industries and companies. Global Co2 emissions [Co2eq], however, have increased from 24 billion tonnes in 2010 to 40 billion tonnes in 2021 (IEA, 2021). Five activities of electricity generation, construction, industry, transportation, and agriculture contribute to over 90% of carbon and GHG emissions. Across those activities, only 40 indicators need to improve for meeting climate goals, and none are currently set to meet their 2030 targets (Boehm, Lebling et. Al. 2021: State of Climate Action 2021). In short, humanity's unsustainability of a fundamental disequilibrium of the anthropogenic system, can now potentially be set in the direction of a new state of equilibrium more aligned to the earth system if the focus is only on 40 indicators [an application of the Pareto principle of prioritisation and choice].

The third is connected to the 1987 Brundtland Commission's key definition of Sustainable Development as 'development that meets the needs of the present without compromising the ability of future generations to meet their own needs' and the 17 Sustainable Development Goals (SDGs). The SDGs with its 169 targets (indicators) are technically supposed to be met by 2030. Available evidence seems to indicate at best, and broadly so, that some SDGs (like SDG9 on industry innovation and infrastructure) are doing better than others (like SDG1 of No Poverty [US$1.90 or less in a day]). To practically achieve the Brundtland Commission's definition of sustainable development at the very least requires the SDGs to be comparable. Comparability requires a theoretical and methodological framework for understanding, defining, and measuring sustainability not just in an integrated manner, but in a manner that is accessible and available to everyone as a shared 'societal value and cultural fact' (Appadurai, 1986; Rosling 2018). A secondary literature review by the authors on keywords "sustainability reporting" "climate change" and "SDGs" found 156 articles, with 73 in "Environmental Science", with 50 in Green Sustainable Science Technology. The result is indicative of a research gap in the field of integrated sustainability measurement and reporting systems that adequately covers Environmental, Social and Governance (ESG) as per the principles of Triple

Development and its practices; and particularly as part of a global efforts to 'reimagine capitalism from an ecological, environmental, politicoeconomic and social lens' (Banerjee and Duflo, 2019; Hendersson, 2020; Vollrath, 2020; Hickel, 2020).

2. Value and Stake: Theoretical Foundations and Practical Gaps

Without anchoring 'value' and 'stake' to a context and its system boundaries, the two terms can become diffused in terms of how it is understood and defined. For this paper, value and stake are positioned within the context of companies and their activities and our current system boundaries of socioeconomic and political processes. Additionally, the two terms are also anchored to Stakeholder Capitalism of WEF and the two concepts of Value Accounting and Dynamic Materiality. From the perspective of an existing theoretical foundation, there is robust body knowledge already available for reference. There is large amount of academic work that argues organisations should move towards a model focussed on sustainable value that 'balances the 3Ps of People, Planet and Prosperity' in its business model, operations and creation of profit and equity. (Edmans, 2020, Magill et al. 2015, Mayer 2018, Schoenmaker & Schramade, 2019, Stout (2012). There is also empirical evidence that by producing a public purpose and a consequent public good [as opposed to a private good] an organisation will create a long-term competitive advantage (Hart & Zingales, 2017). Deriving from the body of work focussing on purpose and sustainability, there is an emerging body of work that focuses on the power of the stakeholders, particularly consumers, to change the behaviour of organisations and companies through their choices, including the choice to exclude behaviours, companies, and products from buying decisions (Kitzmueller & Shimshack, 2012; Besley & Ghatak, 2007).

A stakeholder approach is often considered to be the foundation of "stakeholder theory" (Laplume et.al., 2008), which itself borrowed heavily from strategic management, organisation and systems theories and corporate planning. Stake and stakeholder became important concepts as the social and environmental impact of a company's activities connected to its production and distribution became prominent. The need to document a company's non-financial impact on the larger society led to research that mapped those with a stake [aka stakeholders] and 'their relative importance' to a company. The 'decomposition method of the parameters' (Pallavicini, 1968), for instance, is still the foundation for calculating the ethical, moral, social, cultural, and environmental dimensions of a company's activities, now largely referred to as Corporate Social Responsibility (CSR). Recent research in stakeholder theory has been followed two strands: one focussing on the 'inside out' view of the companies and its operations and the other focussing on the 'outside in' perspective of stakeholders and their connection to the power. The 'inside out' perspective is best exemplified by the work "moral or philosophical guidelines for the operation and management of the corporation" (Donaldson and Preston, 1995). This theoretical approach argues that a company's operation can be understood in three ways. The first is descriptive, where the characteristics and behaviour of firms can be explained in terms of management styles, board or directors and relationship of corporate constituencies like investors and shareholders. The second is instrumental, where data is used to identify

for better profitability and overall efficiency. The third is normative, where the 'moral core' of the firm is identified for purpose [and prosperity] rather than only profit.

The 'outside in' perspective of stakeholder theory (Mitchell et. al., 1997) focuses on identifying the stakeholders within a typology that is based on attributes of power, legitimacy, and urgency. Power is defined as the ability of a stakeholder to impose their will on a particular relationship, legitimacy as the degree of social acceptance and urgency as the acceptance of the stakeholder's claims of time sensitivity. Friedman and Miles (2002) combine these three attributes as a set of 'compatible-incompatible' binaries and identifies eight types of stakeholders, including traditional ones like customers and owners and newer ones like employees and non-government organisations (NGOs). Aligning the stakeholder theory closer to the systems theory [particularly from system-of-systems perspective and the Cynefin framework] has been a growing body of work that also segments stakeholders into normatively legitimate stakeholders, those to whom an organisation hold a legal, economic and moral obligation and derivatively legitimate stakeholders, who derive their status from their ability to affect and influence the organisation or its normatively legitimate stakeholders (Mansel, 2013; Freeman and Moutchnik, 2013; Phillips, 2003). Further, from an empirical perspective of understanding the connection between SDGs and organisations and companies, as a set of stakeholder maps, for example, the work of Rosati and Faria (2019a) use data collected from 2,413 companies in 90 different countries. Their research covers country-level institutional factors that influence the adoption of SDGs in companies' non-financial reporting, such as political and legal, economic, and financial, social, and cultural, technology and innovation, education and labour, and sustainability.

The robust theoretical and conceptual work on sustainable value creation and stakeholder management has not truly translated into any measurable or practical environmental, social and governance (ESG) impact at the ground level. Stake and value, ideally and as per theory, should have co-balanced each other to create a 'virtuous system-of-systems' that would have equitability in terms of wealth generation, income distribution, overall quality of life for all people on the planet and without significant harm to the environment: a key definition of sustainable development as per the 1987 Brundtland Commission report. The lack of such an expected progress is most visible in the steadily rising global Co2eq emissions, a key metric for climate change and global warming. Though close to 96% of 500 of the world's largest companies release their annual sustainability reports, the global Co2eq emissions has steadily increased from around 24 billion tonnes in 2010 to close to 41 billion tonnes in 2021 (IEA, 2021). In short, there seems to be no direct correlation between the increasing quantity and sophistication of sustainability reports and global Co2eq emissions. One of the key expectations of theories of TBL and CSR was that increased focus on metrics and measurement will lead to results. All available evidence indicates that expectation has not been fulfilled in any realistic manner. Simply put, then, there is a gap between theory and practice.

3. Bridging the Materiality Gap: Stakeholder Capitalism and Dynamic Materiality

This gap has been recognised by the corporate world, with some like billionaire hedge fund owner Chris

others like Blackrock CEO Larry Fink referring to 'stark reminder of our fragility – that it has driven us to confront the global threat of climate change more forcefully and to consider how, like the pandemic, it will alter our lives' (Larry Fink, 2021)[2]. It is not immediately self-evident, yet the gap manifests itself in the real world as a materiality challenge. A concrete example is how materiality is instrumentally used to define sustainability as a series of exclusions – also called as negative screenings – can be found in the category of socially responsible investment. According to the Global Sustainable Investment Alliance, nearly two out of every three dollars classified as socially responsible investment are in negative screen fund where the main criteria of including them are from a series of explicit exclusions (say, tobacco or firearms). Such investment funds may be attractive from a market segmentation perspective, but it does very little to track, promote, or reward ESG impact. A 2020 study by Barclay's looked at two decades of ESG investing and found no difference between the holdings of

sustainable and traditional funds, and an investigation by the Wall Street Journal revealed that eight of the 10 biggest ESG funds in 2019 were invested in oil and gas companies. The main problem is that the business idea is normally not included in conceptualisations of sustainable value creation or stakeholder interest and growth. This gap is directly reflected in the GRI standards where value is reported as revenue exemplified by Disclosure 201-1 "Direct economic value generated and distributed". This means that it does not matter from which business the economic value comes from. It could be guns or baby food. The Global Reporting Initiative's (GRI) framework for materiality assessment that is used by majority of companies for their sustainability reporting needs to understood better. The concept of materiality comes from the financial domain. For an auditor, materiality is the determination of the significance of a financial transaction or a discrepancy within a financial statement. The aim of a financial audit is for the auditor, as an independent third party vested with fiduciary responsibility, to endorse that a financial statement covers "all material respects in conformity with the reporting framework of Generally Accepted Accounting Principles (GAAP)." (IFRS, 2022; IASB, 2022). A key materiality principle is that an "accounting standard can be ignored if the net impact of doing so has such a small impact on the financial statements that a user of the statements would not be misled." (IFRS, 2022; IASB, 2022). Translated into an accounting rule, it gives the third-party auditor the flexibility to exercise judgement in deciding if a transaction is material or not.

GRI's materiality assessment framework seeks to mimic the audit and accounting framework for sustainability reporting with two critical pieces missing: an integrated set of sustainability standards similar to GAAP, and a policy, legal, regulatory and governance ecosystem tightly aligned to mandatory compliance and benchmarking. The lack of these two critical pieces positions both the principles of Triple Bottom Line (TBL) – Cradle-to-Gate – and the key materiality framework derived from it – GRI's Scope 1, 2 & 3 disclosure standards for GHG emissions accounting – as a terrain of subjective judgement: companies pick and choose standards and what to report. The authors, at the risk of oversimplification, consider this challenge as akin to the financial community making both the key principles of GAAP – revenue accounting for instance – and the key materiality framework derived from it – balance sheets, profit

Hohn that can be articulated thus: *Materiality assessment today is accurately accounting only for Scope 1 emissions with some degree of accuracy for Scope 2 emissions and practically no accounting for Scope 3 emissions.* Now, including the business idea and putting a stakeholder value on it is no simple task since it requires materiality to be envisaged as a filter of inclusion rather than exclusion.

It is this inclusive filter of materiality that underpins WEF's Stakeholder Capitalism. The concept of Stakeholder Capitalism has existed in some form or another for close to fifty years. In a simple way, it can be understood as a bipolar opposite to Milton Friedman's concept of Shareholder Capitalism, where shareholder value was paramount. Shareholder value is today represented by profit and loss statements and balance sheets, together constituting revenue accounting. Stakeholder Capitalism focuses on creation of long-term stakeholder value, with the shareholders being one of the several stakeholders of customers, employees, suppliers, local community, society, and environment. Klaus Schwab, who proposed the concept of Stakeholder Capitalism, and has been instrumental force behind the WEF's Davos Manifesto 2020 explained Stakeholder Capitalism thus:

Advocates of shareholder capitalism had neglected the fact that a publicly listed corporation is not just a profit-seeking entity but also a social organism. Together with financial-industry pressures to boost short-term results, the single-minded focus on profits caused shareholder capitalism to become increasingly disconnected from the real economy. Many realize this form of capitalism is no longer sustainable.

Conceptually, such a definition transforms a company from a mere wealth generating unit to one that 'fulfils societal and human aspirations, clearly measures and fulfils its environmental, social and governance obligations and creates a balanced and equitable system by limiting and benchmarking executive renumeration to all its renumeration levels and to that of society' (WEF, 2020). By extension, then, a company is also one among all stakeholders, and *not the first* among all stakeholders, creating a "level playing field for global citizenship" (ibid). The September 2020 World Economic Forum (WEF) consultation paper captures the subtle expansion of materiality thus:

The rate at which issues that are currently immaterial become material is accelerating. As observed in recent works, the combination of transparency and rising stakeholder influence is, in part, driving this acceleration… in a hyperconnected world, one in which information can be disseminated widely and immediately… the ability to anticipate stakeholder reactions to emerging sustainability issues and how they could affect a business and its performance is therefore critical. Value-creation plans must optimize performance against current and future material ESG issues. The next stage in this evolution will be the introduction of initiatives that aim to improve performance on ESG issues that are likely to be material for a company in the future. Businesses that do this will gain a competitive advantage and investors that select companies taking this approach – or that encourage their management to do so – will benefit.

stakeholders, with over three-quarters of the respondents agreeing that reporting on a set of universal, industry-agnostic ESG metrics would be useful for their company, financial markets, the economy and for the society. The paper suggests 21 core metrics and disclosures and 34 expanded metrics and disclosures, with the core metrics being a curation and integration of established metrics and disclosures from different standards and reporting initiatives. The core metrics focus on activities within an organisation's own boundaries. The core metrics come under the bracket of materiality and covered currently by GRI's Scope 1 emissions. The expanded metrics aggregates 34 metrics and disclosures from several standards and frameworks that have traditionally been neglected but have a wider value chain scope or convey impact in a more sophisticated or tangible way, such as in monetary terms. They represent a more advanced way of measuring and communicating sustainable value creation. The aggregation, integration and expansion of the metrics and disclosures expands the current scope of materiality substantially. In expanding the scope of materiality in this manner (Figure 1), the consultation paper has set in motion key stakeholders, in particular institutional funders, large international investment corporations, to make the new version of materiality as one of the key conditions for accessing any ESG related funding and sustainability funds. It also turns materiality from a static entity, as it stands today, to a dynamic state. The framework of dynamic materiality blurs the boundaries between the GRI Scope 1, 2 & 3 emission capture norms.

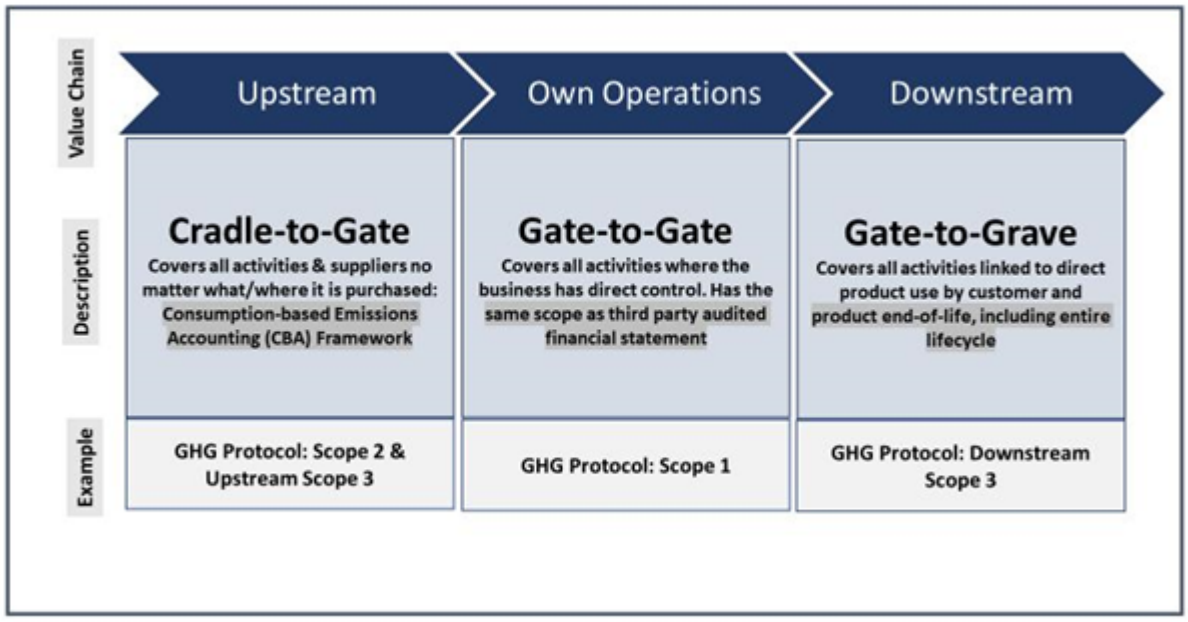
4. The Connection between Dynamic Materiality & Value Accounting

This framework of expanded materiality turns the current understanding of materiality as a static entity, which is how materiality is interpreted today in form of Scope, 1, 2 & 3 disclosure norms, to a state that is dynamic and open to the possibility of continuous change and adaption. Dynamic materiality, as this expanded materiality is often referred to, means two concrete things. The first is that the concept of cradle-to-grave is now segmented into three parts, with each part interconnected to each other: cradle-to-gate, gate-to-gate and gate-to-grave. Additionally, each of these parts are to be put through a value accounting framework (Figure 2) that quantifies the value that each part generates in relation to climate impacts (VBA, 2022)[3].

Figure 2: End-to-End Value Chain Value Accounting



Source: Value Balancing Alliance (VBA), 2022

What this means in practical terms for those directly engaged with sustainability reporting is that they must adopt a value chain approach, at least at the bare minimum as a starting point, to measure carbon footprint and GHG emissions. The same value chain approach must be overlaid on the social and governance dimensions and parameters directly connected to value creation and value addition at each link of the value chain. The second is an explicit acknowledgement that what investors, shareholders, institutions, government, and regulatory bodies consider to be material environmental, social and governance issues will change over time.

[3]Please see: https://www.value-balancing.com/ [Retrieved on 28-01-2022]

One specific case in point is the microplastics in oceans and other waterbodies. The second case in point is the increasing amount of antibiotic resistance and endocrine disorders among the general human population as result of its indiscriminate use in meat and poultry industries.

Dynamic materiality is not something completely new. It has evolved from the concept of double materiality that in simple terms means that materiality is a two-dimensional entity: not only should material topics connected to the enterprise value of a company be reported, measured, and quantified, but also material topics emerging from a company that impact the environment and society should also be reported, measured, and quantified in a comparable manner. In theory double materiality was expected to bring together an organisation's positive impact in terms of profits, growth, jobs, livelihoods, and shareholder value with its negative impact on the society and planet in terms of traditional livelihood loss, sociocultural impact and ecological and environmental damage in an integrated manner and with a common impact score.

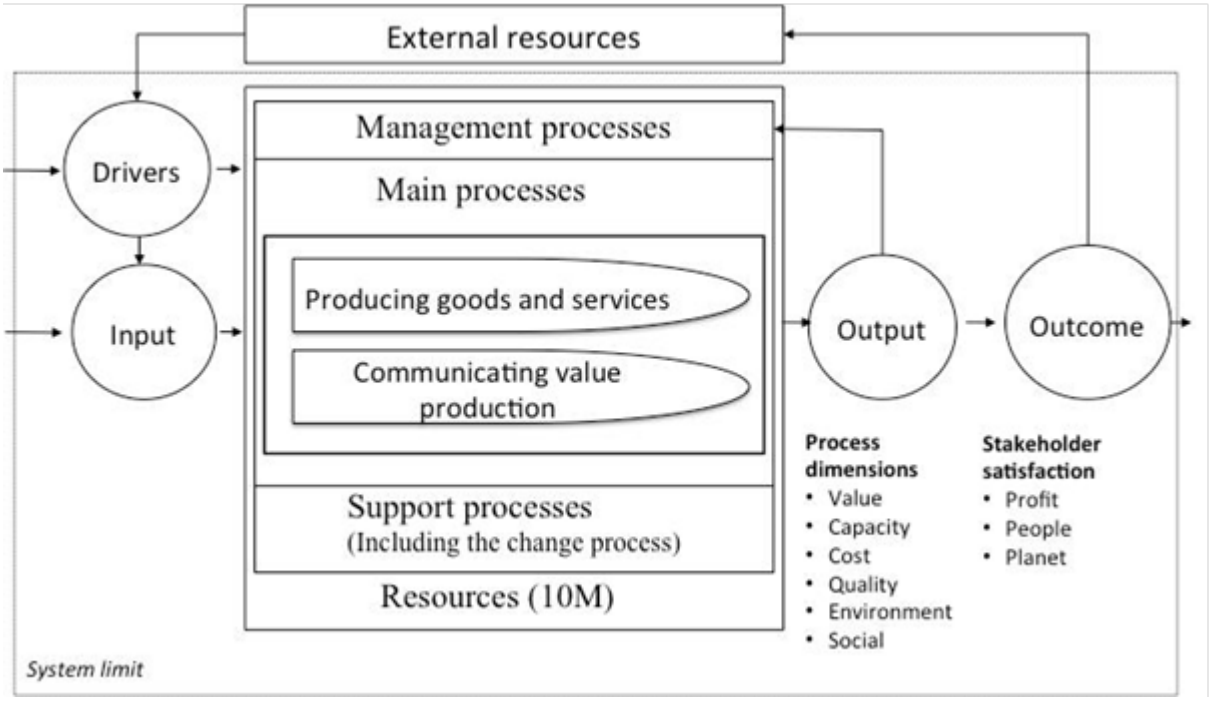
materiality analysis of the enterprise's impact on society and environment. A significant case in point is the proposal adopted by the European Commission in April 2021 to replace the Non-Financial Reporting Directive (NFRD) with the Corporate Sustainability Reporting Directive (CSRD) to make sustainability reporting on par with financial reporting. This makes third-party audit mandatory and on par with financial reporting. The new requirements become effective by January 2023 and sustainability reports as per new standards will have to be submitted by companies in 2024[4].

5. The Process Approach: Engaging with PBSM for Value Accounting

The key distinction between materiality and dynamic materiality is the focus on processes. Traditional materiality assessment was typically a method of exclusion [what is not material], while dynamic material is a process of continuous inclusion [what all is material] with end-to-end value chain mapping [cradle-to-gate] becoming the key foundation. A process-based approach helps understand cause and effect within organisational boundaries (as a key inside out view), and the degree to which they are related to each other. From a value accounting perspective, a Process Based System Model (PBSM) (Isaksson, 2006, 2016) allows for the identification of key system boundaries, specific external resources, main drivers, inputs, management, main and support processes [including activities, tasks, and sub-tasks], outputs, outcomes, and impact. Additionally, there are internal resources [10M] already available within the PBSM for value mapping to done at every level [Figure 3].

[4]Please see: https://www.iflr.com/article/b1w5p4mgfw070q/from-the-nfrd-to-the-csrd-long-story-short [Retrieved on January 24, 2022]

Figure 3: Process-Based System Model



Source: Isaksson, 2016

For dynamic materiality to be converted into a value accounting requires a framework that could capture all relevant steady state parameters across multiple scenarios. Such parameters, additionally, need to be understood and defined from the perspective of value creation. All value creation comes with a certain harm production. Value accounting is a way of understanding, defining, and measuring the balance between value creation and harm generation; to the extent that the ultimate expectation from value accounting is that it will provide everyone with a common shared value/harm framework to understand what kind of productive activities are ideal for creating and maintaining a balance between People, Planet and Prosperity. In short, what *pr*ocesses turn an input into a value-added output and outcome and how much harm does that value creation cause across the 3Ps of People, Planet and Prosperity. PBSM has the potential to provide that framework. PBSM allows the possibility of cross-tabulating multiple factors to evolve an integrated value/harm calculation. For the purposes of illustrating the potential utilisation of PBSM for value accounting from just an input-processes-output perspective, one can take a textile factory in Bangladesh. Giving an able-bodied person in Bangladesh a job in a textile factory is a value, but if the job requires that person to work with hazardous chemicals without protection or exploits that person in any other way, it can be deemed as harm [1P=People]. Using the same logic, if the person is also working with cotton that has not been sourced appropriately, in addition to working with hazardous chemicals without protection, then the harm is multiplied. Alternatively, if the cotton has been sourced appropriated and the famer paid fairly, and the person who in the textile factory is working directly with the cotton is also paid as per globally accepted standards and norms and is not exploited and given adequate protection, then the value is multiplied in the same way vested shareholder value multiples as per current equity norms in stock markets. Similarly, if the same textile factory is using groundwater from the local community for its operations it

and takes conscious part in water recharge and local aquifer regeneration activities then it is value [2P=Planet]. Again, using the same logic, if the factory owners earn megaprofits with rest of the workers and other employees earning a fraction of what the owners earn, then it is harm for overall prosperity, but if the profits of the company are shared in an equitable manner with the employees and to other communities where such activities take, while also contributing to, environmental and economic development, then it is value [3P=Prosperity]. A similar logic, from a value accounting perspective, can also be applied to drivers as well as external resources.

6. Discussion

Sustainability will become a clear and shared societal value only when the trade-offs and incentives of an overall system-of-systems is aligned towards a value accounting framework that starts treating all stakeholders as defined by WEF, and that includes environment, with an equal invested stake. There is a need to move from an actor-network model to a stakeholder model for an 'outside in' inclusive management model. An actor will act only when there is an incentive to act. For example, to smoke a cigarette is an act or to not smoke one is also an act. A person may decide not to smoke a cigarette because it degrades personal health and those around us. In short, the person's awareness about the ill-effects of cigarette is a strong incentive. It is an incentive that is vested in the person as also those around him. An actor will act for constructive improvement only when there is a stake. In short, an actor becomes a stakeholder only when there is a mechanism for the actor to act: capacity to act backed by a capability to act is what makes a stake. For stakeholder capitalism to succeed, sustainability needs to become a societal value and a cultural fact. A value needs a value accounting framework, which in turn needs a process-based approach to understand what value is created in which manner so that the harm generated as result of the value creation is both balanced and compensated in an accountable manner. PSBM has the potential, and needs to be explored for understanding, defining, and measuring sustainability as a societal value and cultural fact.

7. Conclusions

The paper is an initial attempt to engage with the questions of sustainability, materiality. and value accounting. The paper is also part of larger effort to understand the similarities and the potential synergies between quality science and sustainable development as part of continuing research on Quality for Sustainability (Q4S). A stakeholder needs perspective is necessary for sustainability to be operationalised and the Sustainable Development to be measured as per the definition of the Brundtland Commission report. Stakeholder Capitalism expands the notion of capitalism and brings into the fold of stakeholder framework both environment and ecology as equal and key stakeholders as customers, employees, suppliers, and local communities. Additionally, the change in the approach to materiality, from one accounting focused exclusion to one of measurement driven continuous inclusion, is a radical change, allowing for factors that are not even considered to be material at present [for example, massive and irreversible coastal flooding due to climate change] to become part of materiality. Additionally, dynamic materiality provides for such factors to move up and down the scopes, with such factors currently outside system boundaries become

work needed on engaging with PBSM within the developments in Stakeholder Capitalism, Dynamic Materiality and Value Accounting. The ultimate aspiration, and expectation, is to evolve a framework that allows for sustainability to become a shared societal value and a cultural fact.

Operationalizing the regional sustainability assessment by indicators

Introduction

Although there are different currents of thought, the precept that sustainability is perceived from different pillars (economic, social, environmental and/or institutional) can support the Sustainability Assessment (SA) process through the use of Sustainability Indicators (SI).

Although applicable at all scales, the use of SI at the Regional level brings particularities that can infer specific obstacles. Some examples were listed by Wallis et al. (2007), Graymore, Sipe and Rickson (2008) and (Coelho et al., 2010).

- selection of indicators aligned with the sustainability vision of the evaluated area;
- the participation of stakeholders;
- accessibility and condition of the data;
- unavailability of georeferenced data;
- dialogue with the objectives of local and national developments;
- others.

Objective: To try to contribute to this debate, this chapter aims to discuss different operational particularities of Regional Sustainability Assessments (RSA) pointing out methodological paths to overcome challenges that we consider fundamental in the operationalization of the assessment.

Sustainability: a multidimensional concept

There is a definition of sustainable development that is widely adopted worldwide, whether in academic or political literature (Purvis, Mao and Robinson, 2019), and was popularized by the United Nations as one that strikes a balance between the needs of the current generation and those of generations future (UNITED NATIONS, 1987). But (Janouškov, 2018) adds that this definition can serve as a springboard for a variety of interpretations. Despite this, this anthropocentric view of SD pointed out by the United Nations, where economic, social and environmental systems are seen separately, but interconnected, is prevalent.

Multidimensionality that supports evaluation

Gibson (2006) considers that this separation in different dimensions can collaborate with the individual capacities of specialists who participate in the evaluation process, it shows confluence with the way in which much of the data are collected separately, in addition to the institutional structure of governments that, generally, , takes place in a sectoral manner. This supports the use and instrumentalization of SI.

RSA operational gaps and methodological paths

Multilevel interaction in ASR: interregional and intraregional.

For **inter-regional** interaction, Ramos (2009) proposes the definition of a Subset of Common Regional Indicators (SCRI) that should be composed of indicators that have as an intrinsic characteristic their availability for all regions within the scope of national governance, but, at the same time, that each region has its own set of main indicators in order to have a high power of communication of sustainability to decision makers. As for **intra-regional** interaction, the definition of a Subset of Common Local Indicators (SCLI) considering the strategic instruments of the municipalities, based not only on common local resources and characteristics, but also on shared objectives and goals.

Stakeholder participation in the RSA

This participation is especially important at regional and local scales because it is precisely at these scales that there is greater proximity between the community, experts and decision makers, which can represent a simpler and more effective interaction. These stakeholders can be public administration agents, private groups representing companies or industries and the general public with community representatives. Thus, it is possible to obtain a set of indicators that are actually relevant and that measure more precisely what is regionally significant..

Geospatial Approach in RSA

- Spatialization of data for the RSA: the SI are fed with environmental and socioeconomic data, however, due to the nature of the information, these data may have different collection methodologies, and may even be represented in different spatial contexts, resulting in geometric formats of different representations. e.g.

In other words, if, on the one hand, social and economic data are almost always collected considering spatial units that have been defined administratively, on the other hand, environmental data come from their own spatial variation.

- **Geospatialized ASR – 4 examples:**

Graymore, Wallis and Richards (2009) generated a regional sustainability index from a GIS-based decision support model. The authors applied limits that were set naturally and not by administrative standards.

Boggia et al. (2018) proposes the application of an RSA model based on a spatial multicriteria analysis. This approach shows promise for regional assessments as it manages to identify the spatial differences in the region.

Victor et al. (2020) developed a sustainability index on a regional scale where the boundaries represent a spatial interaction that goes beyond discrete objects and starts to adopt a characteristic of continuous fields. This was made possible by using geoprocessing tools.

PSSD (2001) proposes to adopt a subdivision of space into discrete squares, that is, into cells.

Conclusion

Although some gaps persist, here we point out some paths found in the literature in order to provide greater potential to ASR, through the use of IS, to influence decision-makers in taking sustainable initiatives.

Review of participatory approaches for the development of urban sustainability indicators at local level

Introduction

The literature review of indicators systems for assessing urban sustainability reveal a wide diversity of methodologies, involving different types of stakeholders and participation in their development, being necessary to understand the meanings of participation and it's effective contribution to build assessment tools in which there are a better acknowledge of what to measure and how to measure.

So the aim of this research is to conduct a systematic literature review of participatory approaches for the development of urban sustainability indicators at local level.

Methodology

A systematic literature review in the **Web of Science** data base was conducted during the last 20 years. Based on the literature review about participatory processes and local sustainability assessment tools, it is intended to propose an appropriate design, strategies and research methods for the development of an indicator system for urban sustainability assessment.

Criteria and steps used to search references

The following steps was implemented to search references: i) search in the main collection of Web of Science; ii) use of combinations of key words related to the objective of the study; iii) use key words between quotation marks to find exact match; iv) search documents using the option of *all fields*.

Variables used to analyze results

Identified the studies, the variables used to do the bibliometric analysis of the results were: i) categories from Web of Science; ii) authors; iii) affiliations; iv) editor; v) type of document; vi) year of publication; vii) countries/regions; viii) title of publication; ix) research area. Descriptive statistics was applied to explain the outcomes.

Findings

Although the search was successful in finding excellent quality references related to the research objective, the results show the need to refine the literature review, deepening the content analysis performed and promoting the use of the advanced search resources of the Web of Science to find documents that actually include approaches that link participatory processes to the development of indicators to assess urban sustainability at the local level.

Results from systematic literature review in Web of Science

When the *all fields* option is used in the search for documents, many results are reported in different *areas of knowledge* and *WoS categories* unrelated to the objective of the study, which is attested by the content analysis of the respective titles and abstracts, thus serving as an exclusion criterion for documents.

Results from bibliometric analysis

- Key words "participation" and "assessment tools" have a strong connection and are approached for many authors and institutions.
- Expressive concentration of publications is perceived in the last five years, showing the current relevance of the topics.
- Despite a large number of authors, there are frequent and relevant publications by some researchers.
- Some institutions play an important role in the volume and quality of production.
- Only a few publishers were responsible for the great majority of the publications.
- Less than ten journals published almost half of the publications.
- European and North America countries present a more relevant participation in this research area.

Conclusions

Participation or participatory process are important dimensions/key words to link with sustainability indicators; local level; urban sustainability; assessment tools; sustainability assessment; and local sustainability.

It is necessary further developments, especially using deeper content analysis and advanced search resources to refine the literature review and find more focused and relevant documents that can contribute effectively to the study objectives.

As participation is a theme approached in many different research areas with many different objectives, using it for the design of an appropriate strategy and research methods for the development of an indicator system for urban sustainability assessment require a deeper analysis of the references.

Representativeness of Life Cycle Inventory data for olive oil: the Italian case study

Project aim

The Italian project (PRIN – Progetti di Ricerca di Interesse Nazionale 2017- Prot. 2017EC9WF2, sector ERC SH2, Linea C – financed by the Ministry of University and Research) "Promoting Agri-Food Sustainability: Development of an Italian Life Cycle Inventory Database of Agri-Food Products (ILCIDAF)" aims to develop an Italian database of Life Cycle Inventory (LCI) for some agri-food products (Figure 1).

Figure 1. Agri-food chains analyzed in the ILCIDAF project

Some numbers

The olive oil produced around Europe every year is about 2 million tonnes, divided as in Figure 2.

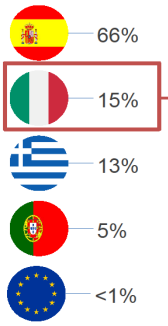

Figure 2. Statistical analysis from average olive oil produced in EU (a) to olive for oil produced in Italy among regions and data gathered (b)

2. Materials and methods

Functional units:

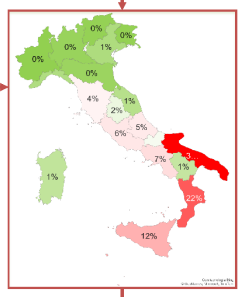
1 hectare (ha) of cultivated land.

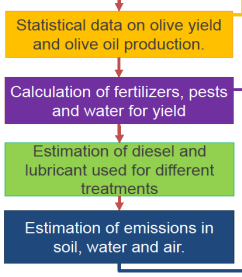
System boundaries:

Soil management, fertilizer and pest management, irrigation plants and water consumption, harvesting and pruning olive trees.

Life cycle inventory (LCI):

Each statistical dataset was built by collecting statistical data from databases such as ISTAT and EUROSTAT. Based on olive yields, fertilizers and pesticides are calculated according to regional technical sheets of integrated cultivation of olive trees. While types of machinery for soil management, fertilization, irrigation, mechanical harvesting and pruning are estimated using the Italian agricultural handbook (Ribaudo, 2017). Then, for each contribution, the emissions on soil, water and air are calculated according to Nemecek & Kagi (2007) and Prasuhn V. (2006).





1. Introduction

The Life Cycle Assessment (LCA) is widely adopted for evaluating the potential environmental impacts of agri-food products. In recent years, its application has experienced a growing interest due to the need to develop a sustainable and carbon-neutral agri-food sector. When assessing agri-food products through LCA, it is crucial the use of primary foreground data able to be representative of the specific technological, temporal, and geographic characteristics of the cultivation and production processes. When primary foreground data are not available, the LCA method suggests to model the Life Cycle Inventory (LCI) using secondary data, such as those available from commercial databases (DBs), in which datasets could provide general information on input and output flows among system boundaries. However, several studies identified the current lack of datasets fully representative of the site specificity of the food product under examination.

In this context, this paper aims to show the highest variability of LCI for agri-food products focusing on olive oil production in Italy. A comparison among the 19 Italian regions' olive oil producers is proposed.

3. Results

Examples of data collected for LCI datasets are reported in Figures 3, 4 and 5, showing the standard deviations for olive yields, fertilizing and related emissions among the19 Italian regions' olive oil producers (excluding Valla D'Aosta).

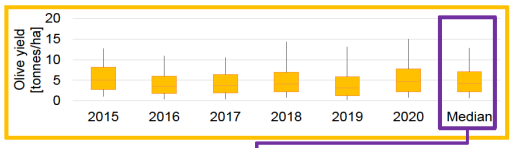


Figure 3. Statistical analysis of average olive for oil yield among regions from 2015 to 2020

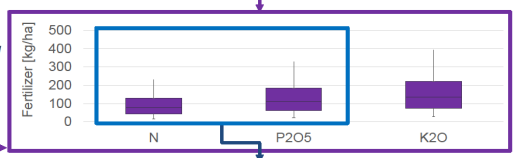

Figure 4. Statistical analysis of average fertilization among regions

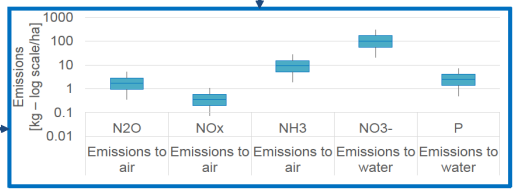

Figure 5. Statistical analysis of emissions generated by fertilization among regions

4. Conclusion

This study presents a partial description of the datasets developed in the project ILCIDAF, highlighting the need to have representative site-specific datasets usable by LCA practitioners to reduce uncertainty in results. The outcomes show that olive production per hectares among regions is about 2 ± 1.21 tonnes. This results in high variabilities of fertilizing inputs that could range from 15.94 (Sardegna) to 101.20 (Trentino) kg of N, from 22.78 to 144,57 kg of P_2O_5, 27.33 to 173.50 kg of K_2O per hectare of cultivated land. Furthermore, these variabilities are also reflected in emissions in air and water, showing the highest variation in NO_3^- emissions (46.80 ± 26.88).

Advancing Care-full Scholarship within the Sustainability Sciences

Professor Alex Franklin[1], Dr Angela Moriggi[2]

[1]Coventry University, Coventry, United Kingdom. [2]University of Padova, Padova, Italy

Abstract

What is care-full scholarship, how is it relevant to the sustainability sciences and how can we teach and learn together about it in a higher education and/ or professional development setting? While as academic staff members we may be fully engaged with our work, how many times have we taken the time, for example, to ask ourselves: 'What, why, and how are we doing research? How do the things we deeply care about influence our teaching practice? In which ways can caring and care ethics help us to change the way we understand ourselves and our interaction with the Earth (Moriggi et al 2020) and prompt us to engage with alternative modes of scholarship?' Beginning with an argument in favour of the potential role of care-full scholarship in furthering sustainability science endeavour, this presentation will then explore how it might be more formally nurtured and enabled in practice. An online open access course, aimed at promoting a care-full scholarship (connectivist) community of learning will be introduced, with session participants given the opportunity to reflect on its relevance and value to their own professional practice as educators, researchers and net-weavers.

Marrying Young: The surprising effect of education

Dr. Madhuri Agarwal[1], Prof. Sayli Javadekar[2], Mr. Vikram Bahure[3]

[1]London School of Economics, London, United Kingdom. [2]University of Bath, Bath, United Kingdom. [3]University of Geneva, Geneva, Switzerland

Abstract

In a traditional marriage market, family's preferences and beliefs over bride types play a significant role in matching. In this paper, we study how an exogenous increase in female education, a preferred attribute in the marriage market, affects her age at marriage. The District Primary Education Program (DPEP) launched in India in 1994, provides a regression discontinuity set-up to estimate the causal impact of education. Using Demographic Health Survey (DHS) 2015-16 data, we find that the program leads to an increase in women's education by 0.8-1.5 years. Next, to see the impact of education on age at marriage, we use the program cut-off as an instrument for education. In contrast to the literature, we find one year increase in education leads to a decrease in age at marriage by 0.44 years. Using a simple transferable utility model, we provide a framework for a negative relationship between education and the age at marriage. As educated and young brides are more desirable in the marriage market, educated women are cleared from the marriage market before less educated women. Further, we find that an increase in education leads to a stable match. Finally, we check if the effect of education on age at marriage varies by the availability of an outside option in the labor market. Our results indicate that educated women in high-wage districts on average marry later than the low-wage districts. A 100 rupee increase in women's wages (25 percent of weekly income) leads to a delay in the age at marriage for educated women by 0.1 years.

The Role of Dilemmas and Paradoxes in Transdisciplinary Research Settings

Prof. Dr. Marlen Gabriele Arnold

TU Chemnitz, Chemnitz, Germany

Abstract

Transdisciplinary research processes empower fast problem identification and problem structuring, allow direct problem solving in cooperation as well as between science and practice and permit the direct integration in research contexts. Knowledge is generated meeting the complexity of today's problems and includes socially distributed knowledge beyond scientific boundaries. In transdisciplinary learning the Agenda 2030 and the Education for Sustainable Development (ESD) can be addressed, including sustainability competencies for implementing the 17 sustainability goals as well as systemic, inter- and transdisciplinary competencies. Hereby, the whole design process and specific tasks and roles of the researchers are impacted.

Indeed, addressing sustainability real-world problems, the acquisition of ESD competencies and the joint work on practice-related problems and questions by scientists and practitioners or stakeholders face role- and task-related trade-offs, paradoxes and conflicts. Fulfilling diverse activities and roles as researchers in sustainability science are part of transdisciplinary settings. This includes being a change agent, knowledge broker, process facilitator, reflective and self-reflexive scientist. Researchers even have to fulfil additional roles and activities when conducting transdisciplinary teaching together with students in transdisciplinary research contexts.

Therefore, the following questions need to be addressed; Which typical tensions, dilemmas and paradoxes need to be faced by researches in transdisciplinary settings?, and How does the role of the researchers change and goes beyond traditional research settings when operating in transdisciplinary settings surrounded by tensions, dilemmas and paradoxes?.

Using existing analytical frameworks of transdisciplinary research design and added by own teaching and researching experiences, main tensions, dilemmas and paradoxes are investigated and evaluated. The empirical part is based on observations of transdisciplinary settings at academia. Moreover, transdisciplinary research and lecture settings will be analysed and compared by transdisciplinary criteria.

Results show, in transdisciplinary settings, researchers or lecturers are more engaged with addressing poly-contextuality, the consciousness of the innovation paradoxes and the side-effects of ongoing interdependences. They take up multiple roles and have to deal with role ambiguity. Transdisciplinary lecture settings are even more demanding as they also have to meet the mentor role or maintain the students' learning progress.

The research contributes to the SDG 4 for ensuring inclusive and quality education for all and promote lifelong learning. Teaching and learning culture as well as the way how sustainability and SDGs are included and practiced are of high importance to laying the foundation for human future. Following the conference's topic of cultural issues learning and teaching setting and interaction foster or hinder a sustainable transition. Changing the learning culture always relates to changing transitory paths towards sustainability.

E-planning for quality school management: A case study in the context of Brazilian public education

Sumara Santos, João Correia de Freitas and João Joanaz de Melo

e-Planning for quality school management: a case study in the context of Brazilian public education

Objectives

This empirical study, carried out in public elementary schools in the Federal District, Brazil, seeks to characterize the use of ICT-supported data in this context, as well as to present practical measures using the e-Planning approach.

The e-Planning agenda includes research aimed at equity, modernization and stakeholder involvement, providing the innovative use of ICT in planning and decision-making processes, enabling new models of participation by the educational community, opening up possibilities for local transformation and improvement.

This approach is in line with the Sustainable Development Goals (SDGs), namely goal 4.1. It is expected that improving school management will also foster educational quality.

Methodology

Strategy
Multi-method research (qualitative and quantitative)
Exploratory, descriptive and correlational character

Participants
115 professionals from 110 schools (Proportional random probability sampling by management complexity level)

Instruments
Literature review
Semi-structured interviews
Digital questionnaire

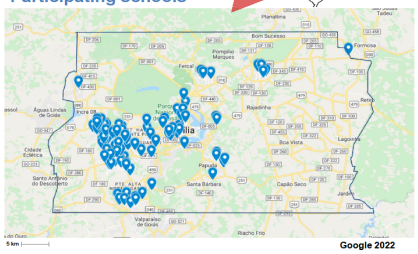
Data analysis
Content Analysis (Atlas.ti)
descriptive and inferential statistics

Case-study

153 Scope - Public elementary schools of 2nd stage of fundamental education: 6th to 9th grade

14 Regional Teaching Coordinations

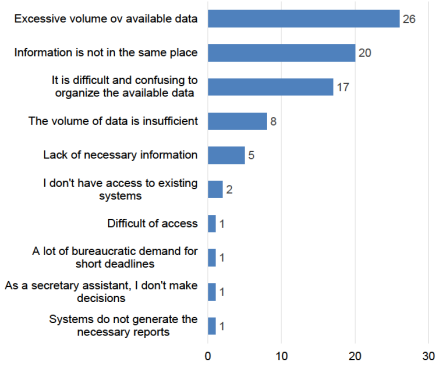
Participating schools



115 Participating (quantitative research)
9 Participating (qualitative research)

Results

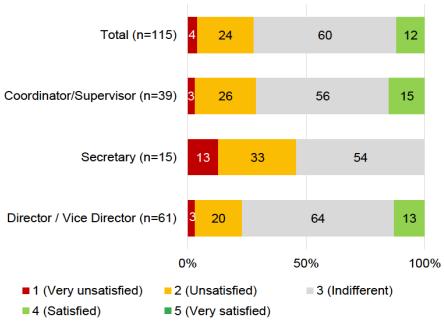
Number of respondents to difficulties faced in accessing information to support school management and decision-making



Benefits and "harms" arising from the excessive use of technologies, difficulty in accessing ICTs, insufficient and obsolete equipment, improvement in the reach of the internet used by the school were pointed out.

In general, respondents were indifferent to the ease of use of digital platforms, their usefulness and completeness, as well as the damage generated by the lack of information.

Community participation assessment (percentage by assessment and job title)



The data point to a reduced interest of the school community in school issues and insufficient participation in the construction of planning and decision-making.

In general, aspects related to the understanding and analysis of available information were evaluated as good. The quality of the communication used was the best evaluated aspect.

Proposals

1. Implementation of decentralized data teams. The effective use of data to inform decisions, achieve goals and solve problems in the school in a sustainable way, providing active community participation in school planning and improving quality.

2. Continuous and participatory internal institutional evaluation mechanism. Empowerment of school actors via ICT appropriation, through participatory instruments.

3. Implementation of electronic management data panel. The need to base education on evidence, with contextualized and interactive data, based on the need to improve the quality of education, with clear and measurable objectives.

Implementation of electronic school management data panel

Conclusions

- The use of ICT-supported data for school management is essential, but not enough, and excess can be a problem.
- The use of data in school management is a dynamic process and the school context matters (e.g. training of staff, background of students…)
- Most school managers recognise that democratic management is fundamental for the good functioning of the school and are aligned with the positive discourse of participation, but… "easy to say, difficult to do".
- Alignment and convergence around the positive "discourse" of participation.
- With the expansion of the use of ICT in the public schools, the e-Planning approach opens up new possibilities to enhance the planning and decision-making processes.

Assessing the Development of Knowledge and Attitude for Sustainable Leadership through Simulation-based Learning: The preliminary findings

Mr. Chatchai Chatpinyakoop

College of Management, Mahidol University, Bangkok, Thailand

Abstract

This empirical study aims to fill the gap in higher education for sustainable development research by studying the use of an online business simulation in a graduate business degree program in Thailand. The main objective of this empirical study is to assess the extent to which the Leading Change for Sustainability simulation, or LCS, impacts students' knowledge and attitude in the domains of change management and sustainability science.

This research will give insight into the impact of simulation-based learning on student understanding of the complex, systemic nature of sustainability challenges and solutions. More specifically, empirical evidence analyzed in this study will offer a summative assessment of the simulation's impact on student knowledge, attitudes, and skills in leading change for sustainability in organizations. Thus, the research addresses a gap in the literature on simulation-based learning and education for sustainable development.

This study uses a quasi-experimental research design to assess change in student knowledge, attitude, and skills related to managing change for sustainability. This study collected the data from classes using LCS simulation taught in a graduate school of management in Thailand. This study is the preliminary result of the data collected from three classes. The pre-test and post-test comprise the sustainability mindset test and the sustainability knowledge test. Half of the knowledge test assessed the sustainability knowledge, and the other half evaluated the knowledge in organizational change management. The attitude test consists of ten questions using a 5-point Likert scale.

From the analysis of the knowledge test, the skewness and the kurtosis of the data, both between -1 and 1. The author also tested the normality of the small sample of this data with Shapiro-Wilk. Both passed the normality test at a p-value of 0.05, reflecting that this knowledge test is normally distributed. The author tested for reliability with Cronbach's Alpha for the attitude test. From SPSS, Cronbach's Alpha for the attitude test is 0.602. It is relatively low but still moderately reliable and acceptable. However, if we took out the item with the lowest correlation, the Cronbach's Alpha improved to 0.632. Therefore, the attitude test of this study is moderately reliable. The paired t-test is used to see a significant difference between the pre-test and post-test in the knowledge and attitude tests. The paired t-tests for the knowledge test passed the t-test significantly. This means that there is a significant difference between the pre-test and post-test scores of the knowledge test. The author also used the paired t-test to assess a difference between the attitude pre-test and post-test and found that the attitude pre-test and post-test are also significantly different. The descriptive analysis of the pre-test and post-test of attitude and knowledge tests also confirmed statistical findings. With these descriptive and inferential analyses, the author can assert that students improve their knowledge and attitude in change management for sustainability from simulation-based learning.

Education for Sustainability: The teaching of skills to achieve the sustainable development goals of the 2030 Agenda

PhD Gabriela Garcez, PhD Renata Bonavides

Catholic University of Santos, Santos, Brazil

Abstract

The dissemination of knowledge is essential and a fundamental requirement for the transformation of society and for achieving sustainable development, based on the Sustainable Development Goals (SDGs), of the 2030 Agenda, of the United Nations (UN), with the objective of enabling all public and private agents to adopt practices that encourage the right to development and protection of the environment, so that it is possible to create multipliers with a positive meaning, organized to contribute to issues related to the right to sustainable development for future generations.

In this way, a profound transformation is required of society to create a world more engaged with issues related to the environment, as described in the SDGs, which must be implemented through the creation of knowledge, skills, values and attitudes that can enable them to contribute to sustainable development (enabled by capacity-building through education, promoted by means of international cooperation and governance).

This is because education is the fundamental instrument in achieving the SDGs, since a change in mentality is necessary about the role of education in the context of global development, as it has an essential impact on the well-being of individuals and on the future of the planet, with the ability to promote values, knowledge and skills that can lead to inclusive, resilient and peaceful growth (on a lasting basis), which promotes economic growth allied to environmental and social issues.

In this line of reasoning, this chapter (through an analysis of bibliographic references, made through a deductive-critical method) aims to discuss education for sustainable development, in order to contribute to the adoption of a new vision in favor of sustainability , in order to enable all interested agents and actors to make more responsible decisions towards the environment based on criteria of integrity, economic viability and fair society for the present and future generations, taking into account that actions already exist at the international level and Brazilian (in the areas of education, international cooperation, governance and the right to development), as well as important regulatory frameworks (such as Brazilian national legislation and international documents) for the promotion of an adequate global sustainable education.

Thus, this chapter is directly related to SDG 4, of the 2030 Agenda, especially with regard to goal 4.7, which, on the other hand, is directly related to the global theme of the conference ("SUSTAINABLE DEVELOPMENT AND COURAGE: CULTURE, ART AND HUMAN RIGHTS"), since it is only through the implementation of adequate knowledge and skills for sustainable development that other human rights can be guaranteed (such as gender equality, promotion of a culture of peace and non-violence, global citizenship and appreciation cultural diversity and the contribution of culture to sustainable development).

Energy: A philosophy of practice

Prof. Natasha Lushetich

University of Dundee, Dundee, United Kingdom

Abstract

Today, 'energy' is most often associated with the global North's – and increasingly the global South's – vital dependence on the combustion of fossil fuels needed for transportation, the production of food, and an ever-increasing variety of commodities. Although there is no shortage of 'green' energy innovations, many cause more problems than they solve, as the example of wind farms in Oaxaca, which caused aridification while reinstating colonial relationships, shows (Dunlap 2018). One reason for this is the sheer volume of energy extraction. The other is the conceptual framework that underpins this activity: this is a source-conversion-end-use concept of energy that is embedded in the Greco-monotheistic-scientific tradition. This conception views the world as composed of individual phenomena, separates animate from inanimate existents, privileges solids over vapours, and teleological developmental trajectories over complexity (Stengers 2018).

Despite the fact that an unbroken line of inquiry can be traced from Aristotle to Einstein, taking in, for instance, Aristotle's notion energy as energeia, entelecheia, and invariance amidst change, the passage from pondering the functioning of levers and pulleys to the discovery of mass-energy equivalence in the 20th century wedded energy irrevocably to technology. Potentiality, which, alongside flux, is one of energy's main 'aggregate states', was reduced to entelecheic end-use. This further gave rise to a 'standing-reserve' view of energy where the actual is 'enframed' within the usable (Heidegger 1977) and where the 'exigencies of planning' entice humans to behave in accordance with what they perceive to be the 'technological imperative' (Glazenbrook 2001). If Heidegger's notion of enframing seems dated, a quick glance at synthetic biology – which modifies biological materials and entities – shows living entities to be a standing-reserve of function (Schyfter 2021).

In the past thirteen years, the post-disciplinary configuration of Energy Humanities has usefully mobilised new-materialist concepts to argue for the relevance of energopolitics to the survival of the planet (Szeman and Boyer 2017). However, Energy Humanities has focused largely on the ethics of energy consumption, which, though useful, does not solve the problem of the crisis of the concept of energy, where the same logic of energy extraction is merely moved to another field, such as datification, which uses unsustainable sources to power data farms.

This paper focuses on reticular (rather than linear) causality in the flux-potentiality continuum. Acknowledging energy's dynamic nature, it proposes a non-dualistic analysis where content (the source of energy) is not separate from method (its technology of transformation). The paper's conceptualisation of energy as a flux-potentiality continuum, and of nature-culture as nature-culture-technology enables an articulation of the full spectrum of energies (not only of primary or secondary energy sources, such as biomass or batteries) that constantly transform our world, through trans-temporal interpenetration of phenomena such as encrustment, encoding, multiplying and re-assembling. The philosophy of practice the paper formulates has three axes: 1. resonance, which comprises physical, spatio-temporal and animal energies; 2. aura, which includes cultural-virtual energies; and 3. assemblage, which consists of the energies produced by arrangements and contraptions.

Geneva, Switzerland. [5]Department of Social, Political and Territorial Sciences, University of Aveiro, Aveiro, Portugal. [6]Ecodynamics Group, Department of Physical Sciences, Earth and Environment, University of Siena, Siena, Italy. [7]Department of Primary Education, Aristotle University of Thessaloniki, Thessaloniki, Greece

Abstract

Massive Open Online Courses (MOOCs) are being increasingly used across all areas of knowledge, including sustainable development. Higher Education Institutions (HEIs) in particular are increasingly adopting MOOCs not just to improve learners' experience, but also to promote lifelong learning for multiple audiences. Given the critical role of HEIs in the transformative shift of values and actions towards sustainability, it is paramount that sustainability education is not only provided to students through formal education but also, in line with SDG 4.7, to the whole university community and the general public within a lifelong context. However, the development of educational tools as MOOCs that can interlink topics such as sustainable development and Ecological Footprint (EF) is still lacking.

Being aware of this lacking, a MOOC entitled “Sustainability and Ecological Footprint: From Theory to Practice” was developed within the scope of the ERASMUS+ project ‘Enhancing Universities’ Sustainability Teaching and Practices through Ecological Footprint- EUSTEPs’; a strategic partnership among four European universities and an international Non-Governmental Organization; to assure the consistency of the project outcomes after the formal end. This paper aims to present and discuss the contribution of the EUSTEPs MOOC on sustainability and Ecological Footprint education as an open resource for lifelong learning. The MOOC is freely available online to all interested target audiences including students, educators, administrative staff, and the general public from within and outside the EU.

This MOOC was made of 50 academic hours and designed according to a hybrid pedagogical model (iMOOC), merging elements from existing xMOOCs and cMOOCs with new collaborative features drawn from UAb's experience with online learning. Based on the outcomes of the previously taught EUSTEPs modules in 2020 and 2021 for the whole HEIs community, this MOOC consists of three micro-credential lessons: i) Ecological overshoot, Sustainability, and SDGs, ii) The concept of EF to promote the knowledge-awareness-action journey towards sustainability in daily life, and iii) The sustainability aspects in HEIs to help the HEIs community to incorporate the sustainability values in all HEI’s missions and practices. Two learning tools are provided for the MOOC: 1) a "Learning Guide" containing the MOOC objectives, syllabus, and learning materials guidelines, and 2) a forum moderated by the facilitators and social media channels to centralize interactions between participants. Universidade Aberta serves as a pilot within the project to test the developed MOOC with their audiences in 2022. Two sets of questionnaires are developed i) a pre-questionnaire to evaluate the expectations before receiving the MOOC, and ii) a post-questionnaire to evaluate participants' perceptions on the MOOC aspects, learning materials, and intentions towards sustainability.

It is expected that by the end of the MOOC, participants will be able to recognize how sustainability and SDGs link with the Footprint concept, and how to promote a sustainable lifestyle, compatible with the one-planet living concept. The revised version of the EUSTEPs MOOC will be made freely available to all interested users, other HEIs, and stakeholder groups as a significant way of disseminating the EUSTEPs rationale and outputs.

Keywords: MOOC, Sustainability, Ecological Footprint

Expanded Learning: Examples of embodied sustainability education practices

Dr Giulia Sonetti[1], Mr Andrea Gerbaudo[2], Mr Andrea Caretto[3], Dr Marco Tonon[2]

[1]CENSE, Lisbon, Portugal. [2]Università di Torino, Torino, Italy. [3]Esculenta, Torino, Italy

Abstract

INTRODUCTION: The current, progressive momentum of environmental sciences, due to the increased attention to climate change does not seem to ground into a significant shift of individual practices, that are sought to be at the root of a new, real change. The so-called 'ecological crisis' is seen by many scientists as primarily an aesthetic one (from the Greek root aisthēsis, that means 'perception'): a sort of inability to perceive what is happening to the Earth as something that deeply affects each of us. More than a question about knowledge, it relates to our feeling and epistemological worldview of westernized humans living in a state of anaesthesia, alienated from the world and disconnected from the interdependent and continually corresponding elements around us, in space and time. Education plays, of course, a crucial role in shaping a new form of Human-Nature-Relationship that perceive humans as Nature, not part of or just connected. GOALS OF THE PROGRAM: Transformative learning, to this respect, aims exactly at shifting from a transmissive to a transformative experience, developing critical and creative abilities, attentive to the different forms of intelligence (human and non-human) and committed to unveiling the complexity and interdependence of the world. This work presents an educational project designed to overcome the division between theory and practice by experiencing the world from an eco-ontological perspective so that participants may develop effective individual and collective thoughts and actions.

PROGRAM DESCRIPTION: The project encompassed three days at the Research Centre for Arts and Science Pianpicollo Selvatico, located in Levice (CN - Piedmont, Italy). The selection of such a place, small and immersed in nature, encouraged free art-making, scientific and philosophical trajectories of thoughts in all forms. Participants were 20 future teachers, either future Primary school ones or Natural Science teachers. We experienced a sustainable style of life, sleeping in tents and eating local food.

EXPERIENCE AND EVALUATION: Through the direct experience of the environment of Pianpicollo, participants perceived a profound relationship with places and communities made of living and non-living beings, in an authentically transdisciplinary ecological perspective. Proposed activities were generative walks, observing and describing the biodiversity of the place, collecting and transforming natural elements and building different handicrafts, from musical instruments to artistic assemblages. Data were collected via a questionnaire before the workshop and via in-depth interviews with all participants. A qualitative analysis, using Grounded Theory methodologies, was then performed to the evaluation of collected materials.

CONCLUSION & RECOMMENDATIONS FOR THEORY AND PRACTICE: Results showed that the majority of participants changed the way of perceiving their connection with living and non-living elements, developing a greater sensitivity towards an alternative way of teaching and learning, experiencing the potential of the place-based and aesthetic-based practices. Education, in this sense, should not only have to do with acquiring specific knowledge but rather by helping each mind and body to be truly present and engaged in our beautiful world.

Exploring Accounting Educators' Perspectives on Sustainability: A Freirean critical pedagogic perspective

Dr Olga Cam[1], Prof. Joan Ballantine[2]

[1]University of Sheffield, Sheffield, United Kingdom. [2]Ulster University, Belfast, United Kingdom

Abstract

Sustainability is a philosophy that is supported by large-scale societal movements. Accounting as a communicative practice, central to organisational decision-making, has the potential to support sustainability agenda. Still in its emerging state, sustainability demands a dialogical learning approach facilitated by educators with a fully awakened critical consciousness and thus can be the force for change. However, the ability of educators to drive the sustainability agenda in accounting education is often taken for granted, which limits opportunities for engagement in critical reflexivity necessary for the critical consciousness awakening. To enable such an engagement requires building the initial knowledge base for learning to understand the view of others (i.e. dealing with relational issues).

This study adopts a Freirean critical pedagogy lens aiming to explore educators' views on the relation of sustainability to accounting (and accounting education). The interview data with twenty accounting educators for UK universities demonstrate that the perspectives of those who teach accounting vary. We map these views that range from the dismissal of sustainability to seeing it as a foundation philosophy for accounting and accounting education along the epochal change continuum. The mapping shows that while change is occurring, sustainability remains of a secondary value to the currently adopted use of accounting techniques as a tool for reporting financial profitability.

The contribution of our study is twofold. Firstly, it explains the evident disengagement with dialogical approaches in accounting teaching. Many educators are confined to a dominant narrow view on the matter and may not yet have an awakened critical consciousness. Secondly, our findings facilitate an opportunity to deal with relational issues for those wishing to engage in self-reflexivity. It enables educators to see the existence of realities alternative to theirs as a firth step to becoming critically awakening educational professionals.

How to Achieve Reduction of Excessive Consumption? An educative approach with middle school students and their families

Fátima Carvalheiro[1], Prof. Sandra Caeiro[2]

[1]Universidade Aberta, Lisboa, Portugal. [2]Universidade Aberta, Lisbon, Portugal

Abstract

The excessive consumption in the last decades is pointed out as one of the main factors of global warning. In order to reverse their consequences, or at least minimised them, it is essential to change the consumption practices. In order to change the consumption behaviours, according to the current standards, nothing better than to involve and motivate the young people So the work had as objective to develop a project about "awareness for the reduction of excessive consumption" with students and their families from middle school, within the scope of education for Sustainability. The target population belong to a school in Palmela, Portugal and the project was developed during two scholar years, from 2020 to 2021. The project was based on an action research methodology that included activities carried out by the students and their families. The activities developed were carefully planned and included: practical and interactive activities, games, collaborative work and seminars. A statistical and content analysis was performed to evaluate the development of the students' knowledge, skills and critical thinking, based on questionnaire surveys and observation grids. The different activities performed with the students allowed them to develop the critical thinking and awareness of unnecessary consumption and its implications. One of the activities consisted in the identification of all the new materials that the students had in their backpacks, recognizing if they had been purchased because they needed them or simply wanted to buy them. By the video visualisation, the students develop knowledge about circular economy, sustainable development, and the evolution of consumption. Moreover, the students carried out individual and group research which allowed them to reflect on topics such as food waste, reuse of materials, sustainable consumption and sales. The final activity consisted in the development of a Strategic Plans for a Sustainable Lifestyle, in the family, at school and in the municipality. Most of all the proposals presented showed that the students were able to reduce their consumption and, at the same time, as well as to be active citizens in the essential community actions. 51% of students and their families were not performing a sustainable lifestyle, however, 37% indicated that they intended to change their behaviour. At the end of the project, 87.5% of the students were willing to change their consumption habits and none indicated "not being available". In last survey it was observed an improvement on the students' knowledge and behaviours. of the most important achievement of this work was the interest of Palmela Municipality to carry out a protocol with the school to develop a project in the same area with the involvement of the students and their families. The results shown the importance of a careful project plan, use of approaches based on system thinking, duration of at least one year, involvement of not only students, but families, school and municipality, and assessment using different tools to allow the achieving of change of behaviours towards a more sustainable patterns of consumption. SDG 4.7; 12.2; 12.5 e 12.8.

In Search of a Sustainable University: Lessons from a Brazilian case study

Ms. Jaqueline Silva Melo, Mr. Eugênio Batista Leite, Mr. Armindo dos Santos de Sousa Teodósio

Pontifical Catholic University of Minas Gerais, Belo Horizonte, Brazil

Abstract

The technological advance of recent times has changed the modes of production and, consequently, consumption. In order to adapt to this new context, an educational intervention became necessary in order to make human beings aware of the importance of preserving nature to guarantee the future, incorporating exemplary practices of sustainable actions in their work processes.

Higher Education Institutions (HEI) can support the construction of sustainability, having the mission of teaching and training decision-makers for the future, they must assume an essential role in the construction of a sustainability project. Based on this premise, PUC Minas defends, in its Institutional Development Project (PDI), shared, participatory and sustainable management. In accordance with the PDI, its Institutional Pedagogical Project (PPI) foresees, as part of its premises, responsibilities for environmental preservation and the need for curricular practices conducive to the sustainable development of the country. Its PDI has a specific chapter for the implementation of practices of sustainability with the proposal of an Environmental Responsibility Program, explaining the theme as an item of its social commitment.

The present study analyzes the actions developed by the Sustainability Commission of a Brazilian university, seeking to achieve the aforementioned goals in the quest to become increasingly a sustainable university, articulating four levels of intervention that are: the education of decision-makers for a future sustainable; the investigation of solutions, paradigms, and values that serve a sustainable society; the operation of university campuses as models and practical examples of sustainability at the local scale and the coordination and communication between all these levels, in addition to engagement with society. The results indicate that the benefits arising from these actions are numerous, highlighting the savings arising from productivity improvements and reduced consumption of inputs; due to compliance with environmental legislation; the generation of opportunities for extension and research, and the expansion of research fields for the university community and, finally, a benefit related to positive gains in the image of the HEI, linked to the challenges of an agenda committed to our own survival.

Marine Litter: Design, implementation, and evaluation of an educational intervention for young people to raise awareness and stimulate co-responsibility and sustainable behaviors

Sara Bettencourt[1,2,3], Carlos Lucas[4], Sónia Costa[3,4], Sandra Caeiro[1,2]

[1]Department of Science and Technology, Portuguese Distance Learning University, Lisbon, Portugal. [2]CENSE - Center for Environmental and Sustainability Research & CHANGE - Global Change and Sustainability Institute, NOVA School of Science and Technology, NOVA University of Lisbon, Lisbon, Portugal. [3]MARE - Marine and Environmental Sciences Centre, ARDITI – Regional Agency for the Development of Research, Technology and Innovation, Funchal, Portugal. [4]OOM - Oceanic Observatory of Madeira, ARDITI – Regional Agency for the Development of Research, Technology and Innovation, Funchal, Portugal

Abstract

Ocean pollution is a global challenge with noteworthy impacts. One of the most worrying sources of pollution is associated with the presence of solid waste in the marine and coastal environment, commonly called 'marine litter'. The recognition of marine litter as an urgent issue to be tackled has been increasing over the years. The problem is indubitably attributed to human activities and behaviors. Therefore, research in education and raise-awareness campaigns has been gaining relevance. The aim of this communication is to present the development, implementation, and assessment of an educational intervention. The intervention's goal is the promotion of sustainable attitudes and behaviors, increasing ocean literacy and awareness among schoolchildren of a small island, Madeira, Portugal, where tourism is the main economic activity. The educational interventions were designed gathering different insights: literature review and gaps identified in pilot interventions. A set of three sessions were implemented and adapted for each class. The sessions include expository presentations, videos discussion, word clouds formation, interactive games, visualization of marine litter objects found in Madeira's beaches, case studies, and practical activities (sampling of microplastics and/or reuse of materials for manual works), according to a reflecting and co-creation learning. Different topics are addressed in each: 1) marine litter definition and impacts; 2) marine litter in numbers; 3) microplastics sampling and individual actions that can be adopted to curb marine litter raise. A fourth session is a beach clean-up action and is optional. Students aged between 8 and 16 years old (third to tenth grade) participate in the actions and fill a questionnaire in the first session (pre-questionnaire) and one in the last (post-questionnaire) to assess changes in knowledge, perceptions, and attitudes. Interventions are being run and by the end of the intervention (April 2022), more than 250 students are expected to have joined. Interventions are evaluated by comparison of the answers obtained in the pre- and post-questionnaires. Altogether, the results indicate that interventions are having positive outputs. Students become engaged with the topic and concerned with the the problem. When data is presented and objects collected in the island beaches shown (e.g. cigarette butts, metal items, balloons) they become worried and perceive that streams, wind, and rain contribute to litter deposition in the marine environment. Students understand that the problem is 'real' in the place where they live and that can impact tourism, economy, and human health, a fact that was not known for much of them (environmental consequences are the leading causes identified). The participants became more aware and understand that human behaviors can contribute to tackling the marine litter issue. The holistic, teamwork, and reflection on action approach that is being used shows to be effective compared to the traditional learning by listening. Future work will consist of adapting the educational actions to other target audiences beyond school students, as marine litter is a global problem that requires an all-inclusive approach.

Philosophy in Nature. Walkshops as a pedagogical-didactical tool for planet proof education

dr Floris van den Berg
Utrecht University, Utrecht, Netherlands

Abstract

'Walkshops' are a new educational tool to enhance teaching in environmental philosophy by taking students outdoors into nature. This paper describes positive experiences with walkshops and how these could be implemented in education in general as a concrete tool towards SDG 4 about education and especially teaching about sustainability or, what philosopher David Orr call 'planet proof education'.

Public Institutions for SDGs: Between didactic (participation teaching method) and social impact assessment

dr Katarzyna Cichos

Cardinal Stefan Wyszynski University in Warsaw, Warsaw, Poland

Abstract

The paper presents the didactic method in the context of organization studies. It presents the new participation teaching method to complement Social Impact Assessment Process in a situation when the organization or public institution (university, local government, etc.) is not aware of either the management of social change, development management methodology, etc. or even the scope of SDGs.

Lack of knowledge and awareness of both SDGs and methodology makes impossible to implement even the simplest solutions from the field of sustainable development within any public institution. Very often, people holding public functions are reluctant to study. Including didactic elements in the SIA process will allow the organizations' representatives (responsible for the preparation and implementation of the sustainable development strategies) to study during the process of development of specific solutions in the area of SDG implementation. Combining the methodology of process of research, planning and the management of social change or consequences with the educational process may contribute to increased public authorities activities and interest in the process of implementing solutions. The research are based on teaching experiment at Cardinal Stefan Wyszynski University

Relations between Universities and Recyclable Material Collectors: An analysis of the production of knowledge in action research

Ms. Jaqueline Silva Melo[1], Ms. Dijana Helena Diniz Costa Vieira[1], Ms. Laísa Santos Magalhães[1], Ms. Aline Rodrigues da Fonseca[2], Mr. Armindo dos Santos de Sousa Teodósio[1]

[1]Pontifical Catholic University of Minas Gerais, Belo Horizonte, Brazil. [2]State University of Minas Gerais, Belo Horizonte, Brazil

Abstract

The actions of universities with the communities, together with teaching and research, make up the principle of inseparability that governs universities, highlighted in Article 207 of the Brazilian Federal Constitution of 1988. The articulation of these three areas enables the transforming relationship that links the University the society.

Our article analyzes the production of knowledge in a university project with cooperatives of recyclable material collectors. The project tries to combine teaching and research in an attempt to mitigate or mitigate the effects of these conditions in order to provide more citizenship, dignity, and safety in the work of recyclable material collectors, professionals so important to society. In addition, we sought to contribute to greater professionalization of the activities of the cooperatives, as well as the promotion of the health of their members.

As urban solid waste can contain valuable materials, people in poverty are involved in the activity, often informal and under precarious working conditions, aimed at collecting recyclable material. Waste pickers constitute a community at risk, not only for their own physical and health integrity but are also subjected to a condition of social and economic marginality, which is often confused with the very concept of garbage or waste.

During the years 2020 and 2021, as a result of the COVID-19 pandemic, the Solidarity and Inclusive Recycling extension project worked remotely in four recyclable materials cooperatives.

The project aims to develop actions that promote the emancipation of cooperatives and their respective members, both in terms of management and human development.

The management axis sought to act in order to assist in the development of the main activity of cooperatives. For this, a management consultancy was carried out, diagnosing the strengths and weaknesses through categories, which were related to financial and material resources, learning and growth, market management, partners and management of internal and operational processes. Based on this, the management axis developed some video classes with topics of interest and made them available weekly to the cooperatives.

The health axis donated face protection masks and basic food baskets to cooperatives, informative booklets for waste pickers with a focus on preventing the contamination of COVID-19. Surveys were carried out on the health and ergonomic profile of the collectors, food health, and zoonosis conditions in the cooperative. From this, videos were produced about men's and women's health.

The communication axis carried out a survey to analyze its communication profile. After this survey, a communication plan was developed, and a project page was created on Instagram and YouTube, which made it possible for the actions carried out to be disseminated on social networks. In addition, the project held conversation circles on topics related to recycling, which made it possible to share knowledge between the academic public and the cooperative members.

This action is related to SDG 10 (Reducing inequalities), providing waste pickers with access to tools and techniques that can assist in their personal and professional growth, meeting target 10.2 whose objective is to empower and promote social, economic inclusion by 2030.

Short-term and Long-term Impact of Education for Sustainability on the Behaviour of Students

Ágnes Zsóka, Katalin Ásványi

Corvinus University of Budapest, Budapest, Hungary

Abstract

Knowledge and recognition of sustainability issues are a prerequisite for changing society's mindset, attitudes and behaviour towards sustainability. Universities have a key role to play in developing sustainable culture and providing students with the knowledge they need to think and act in a more sustainable way, as set out in SDG 4.7. goal which also states that „all learners acquire the knowledge and skills needed to promote sustainable development and sustainable lifestyles". Recently, more and more universities have integrated a sustainability approach at the level of study programmes or courses that promotes the development of sustainable consciousness along knowledge, attitudes, and behaviours. Examining the impact of courses on some elements of sustainability consciousness or its complexity is a less researched field, and examining its long-term impact has appeared in few research so far. After exploring the literature on sustainability consciousness and the relationships among its elements, a specific course on sustainability was examined over four semesters (Fall 2019, Spring and Fall 2020, Spring 2021). A special feature of the project-based course is that students work with a community partner each semester. The aim of the course is in line with SDG 12.8. goal, that ensures that students „everywhere have the relevant information and awareness for the sustainable development and lifestyles in harmony with nature". The changes in the students' sustainability consciousness achieved by the course were examined by structured in-depth interviews, in two phases. The first measurement was taken at the end of the course (short-term impact), the second one was in the fall of 2021 (longer-term impact). At the end of the course, structured in-depth interviews were conducted with a total of 200 students over the four semesters, during which they reported on their own perceived knowledge, attitudes, and behaviour. In the phase of the longer-term measurement, 30 interviews were conducted. Findings show that at the end of the course, students clearly show a higher level of knowledge in sustainability issues, more positive attitudes, and more openness to developing sustainable behaviours. Different community partners had a different impact on students' consciousness: when students worked with a partner focusing on social problems, the shift towards social sustainability was stronger, while an environmental NGO as partner strengthened environmental consciousness more distinctively. The long-term impact of the course is less pronounced: students lost some of the acquired knowledge and some sustainable behaviours have worn off in their daily lives, while positive attitudes remained almost the same. Results suggest that one single sustainability course has a limited long-term impact. There is a need for continuous impulses and additional courses for students at the university, to encourage change in behaviour towards sustainability and deepen sustainability consciousness in the longer run.

Teaching to Embrace Uncertainty – using SDGs as shared objects

Dr. Steffi Siegert, Dr. Malin Gawell, Dr. Paul Fuehrer, Dr. Ann-Sofie Köping

Södertörn University, Stockholm, Sweden

Abstract

In this paper we reflect on the development of an international, interdisciplinary master programme in the social sciences and on challenges related to teaching sustainability on an advanced level. Special focus is placed on how the sustainable development goals (SDGs) can be used as "shared objects" in both programme development and teaching. Our empirical material consists of interviews with involved academics, and notes/documentation from workshops and seminars with researchers and external partners before the start of the programme. We furthermore include an analysis of students' master theses and their understanding of sustainability shown in the texts. The main emphasis was put on differences in the definition and perception of sustainability, the recognition of SDG as shared objects and various ways to manage these challenges in higher education. The SDGs have been a useful tools to frame and start discussions on sustainable develop. Gradually, diverse and ambiguous views, perspectives and interpretations have been more noticeable. This has challenged the role of the SDGs as a shared object.

The students had, as expected, diverse views on sustainable development and varied knowledge of the SDGs. They also had very disparate experiences of different types of teaching. Not all were used to group work or to the student driven learning approach that has been implemented in the programme. Even if these pedagogical challenges had been discussed already during the planning process, it has been obvious that they have been underestimated – especially in relation to the need for support on what Vigotsky refers to as "zone of proximal development" of the understanding of the SDG and how they are related to sustainable development.

This leads to primarily two future tasks for the core team of teachers/researchers. Firstly, there is a need to further explore and develop the relations between SDGs as well as other views on sustainable development. This is pertinent in relation to social science perspectives on social and cultural aspects of sustainable development. Natural sciences' perspectives on environmentally sustainable development appear to be more well defiend and easier to operationalize, measure and apply to practical problems However, the social and cultural dimensions are as important for a transformation towards sustainability.

Secondly, there is a need to further develop the pedagogical approach to embrace uncertainty through attention to the diversity of students and their learning processes in the zone of proximal development so the SDGs can be given a clearer role not only as shared object, but as transitional object in line with Winnicott's ideas about objects of comfort as safety during challenging transitions. Our experience from the programme's first years is that the SDGs can be used as shared objects in order to frame collaboration and teaching for sustainable development. But the experiences also show that the focus on the SDGs as such, risk to encourage a rather shallow view on sustainable development. The focus on SDG does not automatically lead to a nuanced view on sustainable development.

The Impact of Teaching Engineering for Sustainability on Students. A comparative study on different levels of sustainability integration in University of Technology

PhD student Claudine Gillot[1], PhD Student Lou Grimal[1], PhD Yacine Baouch[2]

[1]InSyTE, Creidd, Troyes, France. [2]Université de Technologie de Compiègne, Compiègne, France

Abstract

Engineering training has been transformed through the last decades for the integration of sustainability into engineering classes. Those evolutions are quite difficult as education for sustainable development is a real challenge to implement. Indeed, integrating sustainability requires new competencies (for instance critical thinking, systemic thinking, self-knowledge) and knowledge (technical, environmental, and social knowledge), attitudes, and values. More knowledge on how to teach those elements is required. In this paper, we focus only on the competencies for engineering education, as those competencies are well defined in the literature and as there is a lack of examples of implementation of those competencies. Thus, the goal of this paper is to better understand the impact of teaching sustainability to engineering students and to what extent the way we teach has an impact on the evolution of competencies of students for sustainability engineering.

Different forms of integration and ways to understand sustainability exist and are supposed to have different impacts on engineering students. To address our goal, we have explored three different forms of integration of sustainability, from weak to strong sustainability, and from a standalone class to a master's specialization on sustainability. We conducted a comparative analysis with three different classes which integrate sustainability differently in their engineering curricula, at different levels of class. This case study will be scrutinized thanks to an analysis of competencies of engineering for sustainability (qualitative and quantitative analysis). The competencies of students have been evaluated at three different moments in a class (at the beginning, at the middle, and at the end of the class) through self-assessements.

With this study, we yearn to better understand how to implement the teaching of engineering for sustainability competencies. There are two outcomes of our work: (1) a better understanding of the role of education in the improvement of competencies of engineering for sustainability and (2) a better understanding of possible ways to measure the improvement of those competencies among engineering students.

The Regenerative Campus and Sustainable Wellbeing - an exploratory literature review on nature-based and transformative approaches in higher education institutions

MSc Carolina Silva[1], Dr. Antje Disterheft[1], Prof. Dr. Matthias Barth[2,3]

[1]CENSE—Center for Environmental and Sustainability Research, NOVA School of Science and Technology, NOVA University Lisbon, Campus de Caparica, Caparica, Portugal. [2]Institute for Sustainable Development and Learning, Leuphana University of Lüneburg, Lüneburg, Germany. [3]Presidency, Eberswalde University for Sustainable Development, City Campus, Eberswalde, Germany

Abstract

Education for Sustainable Development (ESD) in higher education institutions (HEI) plays a crucial role in the debate about sustainability and societal transformation to achieve the 2030 Agenda and the Paris Agreement. However, links between holistic learning and nature-based solutions in and for HEI are still under-researched topics. Learning in and with nature can contribute to people's overall wellbeing and lead to transformation on a personal and collective level. At the same time, such holistic learning approaches can provide innovative ways to mitigate and adapt to climate change. This research wishes to understand better how education in close contact with nature can transform people, as well as their perception of their existence and sustainability mindset. Embedded in a larger PhD project, this work presents the results of an exploratory literature review that shall serve to understand better the state of the art of concepts of nature-based solutions, transformative learning, nature connectedness and wellbeing in HEI, and to find out about already existing initiatives in HEI that follow holistic learning approaches and have implemented nature-based solutions on campus. The deep leverage points for transformation (Abson et al. 2017) will be used as selection criteria to map those HEI, namely (i) how the institutions are structured in comparison to other regular sustainable HEI (e.g. how HEI are overcoming disciplinary separations of faculties and departments, which are the notable differences in their curriculum, how are the fees' costs and means of access, etc.); (ii) how the HEI reconnect people to nature (e.g. the existence of outdoor spaces for classes and other extra activities, a campus garden, a campus forest, etc.); (iii) how knowledge is created and applied for sustainability (e.g. through the inclusion of embodied knowledge, indigenous wisdom, etc.). . The results will help to identify how nature-based and transformative approaches might differ from more conventional sustainability approaches, and invite actors in education towards taking more courageous steps for reaching the SDGs, namely SDG4, target 4.7, and SDG13, target 13.3. We perceive rethinking education and educational institutions as an act of love and courage, and we therefore regard our research well aligned with the conference topic: holistic educational approaches that connect people to nature and consider different aspects of the knowledge production in HEI, including arts, promote existential and philosophical changes that can contribute to the adoption of a more sustainable and harmonious way of life and hold the potential to transform our society effectively towards a more sustainable world.

The Educational Worldview Journey. A transformative learning tool for exploring, exchanging, and expanding perspectives in a world in crisis.

Ph.D Annick de Witt[1], Ph.D Margien Bootsma[2], Ph.D Karin Rebel[2]

[1]Wageningen University, Wageningen, Netherlands. [2]Utrecht University, Utrecht, Netherlands

Abstract

As complex planetary challenges like climate change demonstrate, sustainability issues are often characterized by high degrees of public polarization and a politicization of scientific knowledge. Due to the planetary challenges and systemic crises the sustainability field is inherently focused on, calls for more transformative approaches are also common. Building on ideas and findings from systems thinking, transformative learning theory, and developmental psychology, transformation can be understood as a shift of perspective – i.e., a "mindshift", "paradigm change", or expansion of worldview. Engaging with our foundational paradigms or worldviews is therefore particularly potent, as it allows us to create more transformative forms of (sustainability) education, while also responding to the extreme cultural polarization that characterizes contemporary society more generally, and our sustainability issues in specific.

In this presentation, we aim to share our findings with respect to our project of designing transformative education in the context of sustainability education at a modern Higher Education Institution in the Netherlands, which we'll present here as case-study. As a diverse group of educators and researchers at Utrecht University, we've developed a continuous learning tool, the so-called Educational Worldview Journey (EWJ). The EWJ aims to put more emphasis on students' ability to take different perspectives, critically reflect on their own perspective, and understand the central role of perspectives in the understanding and 'framing' of sustainability issues and their solutions more generally. Moreover, the EWJ intends to invite for, and facilitate transformation, next to providing students with information.

In the EWJ, we use the concept of worldview as an entry-point for this exploration. That is, rather than just being embedded in their worldviews, students are supported to look at them. In a step by step process, students are invited to explore their own worldviews, constructively communicate with those of other worldviews, and reflect on their worldview in a world in crisis, aiming to clarify their role and purpose in the larger whole. About 1000 students completed the level 1 of the EWJ (level 2 and 3 are still being finalized). The experience was highly valued by a great majority, and their evaluations offer interesting insights into what higher (sustainability) education may derive from such an approach. Particularly noteworthy was students' willingness to reflect on, and acknowledge the inherent limitations of, their own perspectives, as well as their eagerness to learn about, and communicate with those of, other worldviews. As we will argue, a systematic exploration of our individual and collective worldviews could be a potent entry-point for starting to address some of our larger societal and sustainability challenges.

This contribution can be said to relate in particular to SDG's 4 (quality education); 16 (peace, justice, and strong institutions); and 17 (partnerships for the goals), and speaks strongly to the conference topic, by focusing on the cultural dimensions of our sustainability issues as well as cultivating the kinds of courage, cultural exchange, and collaboration that are essential to addressing them.

Universities Driving Sustainability: Exploring cross-cultural pathways to a circular economy of plastics on campus

Jana Busch[1], Prof. Pauline Deutz[1], Dr Felix Why[1], JProf. Julia Affolderbach[2], Prof. Hồng Quân Nguyễn[3], Phúc Trần Thị Diễm[3], Asst. Prof. Niwat Srisawasdi[4], Chawadol Sriboonpimsuay[4]

[1]University of Hull, Hull, United Kingdom. [2]Trier University, Trier, Germany. [3]Vietnam National University, Ho Chi Minh City, Vietnam. [4]Khon Kaen University, Khon Kaen, Thailand

Abstract

In recent years, the problem of extensive waste generation, especially plastic waste, has been placed at centre stage in environmental debates. Consequently, universities, whose various complex activities facilitated on campus (space of working, studying, socializing, consumption and living) result in significant material consumption and waste generation, are interested to improve their environmental performance by tapping into Circular Economy approaches. Existing research findings, predominantly focusing on universities located in the global north, have shown successes of reducing waste on campus by universities implementing, testing, and bringing forward circular economy approaches. But how much does that depend on local context and cultural habits on university campuses? The study explores findings of ongoing cross-cultural research conducted at universities in four countries: the UK (University of Hull), Vietnam (National University Vietnam), Germany (Trier University) and Thailand (Khon Kaen University). Ethnographic research methods are applied to back the practice theoretical approach of the research project. Observation methods on campus, interviews and surveys conducted with the university populations and experts and affiliated stakeholders of the university are included in the data collection. Research methods were designed and trialled at the University of Hull and adapted to the context of the other universities where needed. The four case studies draw a picture of a cross-cultural comparisons of the constitutions, drivers, and challenges of a circular transition on campus. The research project relates to the implementation of SDG Target 11.6 'By 2030, reduce the adverse per capita environmental impact of cities, including by paying special attention to air quality and municipal and other waste management', Target 12.5 'By 2030, substantially reduce waste generation through prevention, reduction, recycling and reuse and Target 17.17 'Encourage and promote effective public, public-private and civil society partnerships, building on the experience and resourcing strategies of partnerships Data, monitoring and accountability'. The research project relates to the Conference's theme by exploring courageous progress towards sustainable development in times of global crises in the context of university campuses across international cultures.

Walkshops towards a Sustainable World. Teaching environmental philosophy in the woods

Dr. Floris van den Berg

Utrecht University, Utrecht, Netherlands

Abstract

Most of school and university education takes place inside artificially lit classrooms where students sit on chairs and listen to their teacher. Especially when teaching environmental philosophy, it seems awkward to teach *about* nature, but not *in* nature. Is it possible to gain a deep understanding of our alienation from nature by remaining indoors? For the last ten years I have been experimenting with different kind of outdoor education with students. I have developed the concept of a walkshop (from 'workshop' and 'walking') where I take students out in the woods for a diverse program of doing philosophy while walking. Based on topics related to environmental philosophy (e.g. deep ecology, the SDG's, the concept of nature, intrinsic value, natural beauty) students walk in pairs and have conversations about these topics. Pairs are changed several times. In order to create more awareness of nature, there are periods of silent walking. One of the highlights (according to students) is a session of tree hugging. Most students have heart of tree hugging but never actually hugged a tree. Doing that for 20 minutes changes the awareness of what a tree is, but also of yourself. Blindfold walking, where one is guided by a fellow student (and only the blindfolded person is allowed to talk) creates a quite different experience in raising the awareness of hearing and building trust. Yet another aspect of the walkshop is to create in a team **land art**, that is playfully arranging things in nature without destroying anything. The sheer joy of seeing adults play like small children is amazing.

Walkshops are active and interactive and involve much more than cognitive skills. From students evaluations it has become clear that even a one day walkshop in the woods can have profound influence on a person's perception of nature and life stance. Solutions for sustainability cannot only be technological fixes, but also require a different attitude toward nature. Outdoor philosophy education seems a promising way to help change the attitude towards a more deeply felt connection with nature, and reflecting on how being outdoors in the woods, walking and reflecting can help to build a meaningful life. Walkshops seem very well suited for Education for Sustainable Development. These wonderful experiences raise the question if walkshops can be implemented in education on a broader scale.

The topic of outdoor education in environmental philosophy is relevant for SDG 4 (Education), target 4.7: Education for Sustainable Development. In order to change mainstream class room education to include outdoor education, it takes **courage** from teachers and staff from standard educational practices. Walkshops are about changing the mainstream cultural paradigm of materialism to a meaningful playfulness of being outdoors in nature: not buying stuff, but walking. Not facing a screen, but facing the sky. Not sitting passively indoors, but actively walking outdoors. Not thinking about nature, but thinking about nature *in* nature.

Creativity, Leadership and Education for Sustainability

A *Creativity in Action Project* to support student learning, action and impact for sustainability change

Jayne Bryant[1,2]

[1]*Blekinge Institute of Technology, Sweden, jayne.bryant@bth.se*
[2]*Curtin University, Australia*

Abstract

The sustainability challenges of our time require engagement from all, and the potential for the arts and humanities to contribute has been undervalued and underutilized within sustainability science approaches. UNESCO sees education is seen as a key leverage point to shift society towards sustainability transformations however as with sustainability approaches in general, the potential of creativity and the arts remains untapped as a tool, topic, process, pedagogy and way of thinking. Inspired by a creativity assignment delivered in a Leadership in Sustainability course at Curtin University in Western Australia, this paper describes a Creativity in Action Project which was an assignment within the Advanced Leadership for Sustainability course at Blekinge Institute of Technology in Sweden. It was a year long course that ran through 2021. This paper articulates the purpose, design, pedagogy, content and learning process of the Creativity in Action Project and how it integrates the whole course. In brief, the students were invited to: "...explore the role creativity and/or the arts play, or could play, in expanding your thinking and in shifting paradigms that move people towards sustainability" and the intention of the project was to "...explore creative ways to enact change for sustainability in your lives or communities" through taking inspiration from artistic practices and processes. Through a feedback survey from the students, this study evaluates the project as a whole and identifies the key pedagogical elements that supported the students learning; what provided value and impact for the students; as well as discussing the challenges in doing such work. With permission from the students, this paper showcases some of the artistic and creative projects that the students completed. The intention of this paper is to provide educators and learning designers with inspiration and a practical, adaptable, and impactful creativity-based pedagogy for the development of sustainability leadership and key sustainability competencies that could be used and adapted to various contexts. It is hoped this will in turn support societal transition towards sustainability through empowering students to be sustainability change agents by applying their creativity to solve a sustainability challenge in real life.

Keywords: Creativity, Key Sustainability Competencies, ESD, Leadership, Sustainability

1. Introduction

The sustainability challenges of our time call for new ways of education that produces graduates capable of creatively approaching the many problems we face (UNESCO et al., 2020). It will require engagement from all, and the potential for the arts and humanities to contribute has been undervalued and underutilized within sustainability science approaches (Palsson et al., 2013). To move towards a more sustainable society will require large scale transformations of our structures and systems and human agency, or leadership, is a key leverage point to do this (Abson et al., 2017; Bryant & Thomson, 2021). The change required within society will be one of social learning in its broadest sense (Barth & Michelsen, 2013) and with education as a key leverage point, much research has been produced to guide educators and practitioners on the key sustainability competencies required by graduates of sustainability education (Wiek, Withycombe, & Redman, 2011). More recent additions to this work introduce two newer competencies: the Implementation Competence (the ability to enact change for sustainability in the world), and the Intra-personal Competence (the ability to avoid burnout in implementing sustainability transformations through resilience-oriented self-care) (Redman & Wiek, 2021). Further research on the best ways to support the development of all of these competencies is still needed (Brundiers et al., 2021). As with sustainability approaches in general, the potential of creativity and the arts remains untapped as a tool, topic, process, pedagogy and way of thinking in Education for Sustainable Development (ESD) (Newman-Storen, 2014; Sandri, 2013).

The Cambridge Dictionary online defines 'creativity' as: "the ability to produce or use original and unusual ideas" (UK) and adds the phrase "...or to make something new or imaginative" to the US version. Creativity has clear benefits for individuals and society and does not just play a role in the arts, invention and innovation but in our everyday lives (Runco, 2004). Research into creativity can be grouped into four main areas: the creative *person*; the creative *process*; the *product* that is the result; or *press* – which refers to the situational influences or environmental support for creativity (Runco, 2004, p. 664). This paper presents a pedagogy – a Creativity in Action Project (CAP) - which invited students to participate with the foundational assumption that all *persons* are creative in various ways and forms, and all have the ability to produce a creative *product* through a creative *process*. The *press* – the situational or environmental influences that often support creativity are "freedom, autonomy, good role models, resources (including time), encouragement for originality, freedom from criticism and norms in which innovation is prized and failure not fatal" (Witt & Beorkrem, 1989, pp. 31–32). These reflect the conditions that we attempted to create to support student learning about themselves, the role and value creativity can play in addressing sustainability issues in their lives and work, and as a pedagogy to support the development of key sustainability competencies in the participants.

1.1 Context and Background

The Creativity in Action Project (CAP) was an assignment within the Advanced Leadership for Sustainability (ALfS) course at Blekinge Institute of Technology (BTH) in Sweden which ran through 2021. All students were required to be graduates of the Master's in Strategic Leadership towards Sustainability (MSLS) to participate, and the ALfS course built on concepts and relationships that are incorporated in that program (see e.g., Bryant, Ayers, Missimer, & Broman, 2021). It was a stand-alone course delivered online and was worth 15 credit points. The CAP was worth 2.5 points of the total course and the other assignments were two "Written Portfolio" deliverables (10 credits), and a "Learner Led Session" (2.5 credits) where they researched and then taught in groups topics they were interested in, to the class.

1.2 The CAP Assignment

For this assignment students were invited to explore the role creativity and/or the arts play, or could play, in expanding their thinking, and shifting paradigms that move people towards sustainability. It encouraged them to play with new ways of enacting change using creativity and the arts for inspiration. The CAP was inspired by a similar creativity project conducted in a Leadership in Sustainability course which I have also been involved in co-designing and teaching at Curtin University in Western Australia (see: Mouritz et al., 2022; Newman-Storen, 2014).

The deliverables for the CAP assignment were:

- The CAP project itself
- An individual Reflection Essay (500 words) on the lessons learnt in doing the CAP

The CAP could be done individually or in small groups and could be: "a process or product or thing or event that you must be able to present/show/demonstrate to others". In this project students were asked to use a unique and creative method to enact change for sustainability in some way:

"...to play, learn, dance, prototype, paint, sing or just take inspiration from these artistic practices to enact change in a way that is unique, novel and untried thus far for you. The intention of the project is to explore creative ways to enact change for sustainability in your lives or communities. Think of the output of this project as an exhibition which will be captured on a webpage on Canvas where you share your project and other students can read/see/experience your work."

Students were encouraged to stretch towards new ways of thinking, being and doing rather than producing an intervention or creative work of the utmost 'quality', 'beauty' or 'success'.

The pedagogical elements of delivering the project were:

- The online learning platform used at BTH is 'Canvas' which is used for all teaching – both distance education (online learning) and face-to-face. BTH changed to Canvas in 2018 as it has been designed to support education both in person and at a distance.
- The CAP content on Canvas included:
    - Introduction Video explaining assignment
    - One Required Reading (Newman-Storen, 2014)
    - Recommended Readings (Cameron, 1992; Jaworski & Flowers, 1996; Kagan & Kirchberg, 2016; Kajzer Mitchell & Walinga, 2017; Lozano, 2014; Molderez & Ceulemans, 2018; Palsson et al., 2013; Runco, 2004; Sandri, 2013)
    - Videos such as 'Do Schools Kill Creativity?' by Sir Ken Robinson; and 'Your Elusive Creative Genius' by Elizabeth Gilbert
- Creativity in Action 2-hour online class sessions (March and September 2021)
- One-on-one coaching sessions (offered at various times throughout the year)
- An 'Exhibition Space' on Canvas where students shared their project and work
- An 'Exhibition/Showcasing Event' at the end where students shared their projects and shared their lessons learned through doing the project.

Grading was pass/fail and participation in the project (and presentation through images, a weblink or description of what they did on the Canvas webpage), and submission of a Reflection Essay were the criteria to pass.

2. Research Methods

As a teacher and designer of this course and the CAP I identify as a 'Reflective Practitioner' (Schön, 2003). A primary goal of this study is to reflect on the work and course, to gather insight from participants and to offer the learnings for other educators of ESD. The primary data gathered include my own reflections from the experience of designing and teaching on the course; a 10-question survey which 21 out of 24 students responded to; and the artifacts of the creativity project shared predominantly as images. In this section I describe my own reflections which shaped the survey development so I will use the first person.

Through facilitating the final Showcase/Exhibition and reading the Individual Reflection Essays which the students were required to reflect on their CAP, I noticed the joy and pride at overcoming challenges and stretching comfort zones. I observed courage in their actions and found it interesting how some focussed on 'inner change' (of themselves) and others focussed on trying to create change for sustainability outside themselves. A further deliverable for the course was for students to provided "Written Portfolios" which are also a reflective pedagogy (Ayers, Bryant, & Missimer, 2020), some other teachers who were also teaching on the course told me how some of the students shared how important the creativity project was for them. This initial sense-making involving my own reflections on the CAP informed the design of the survey. The Survey consisted of 10 questions, predominantly open-ended questions with two quantitative questions. The 24 students who completed the CAP were emailed and invited to participate and 21 responded. Information about the study was provided in the email and at the beginning of the survey and the first questions were regarding consent. Students were invited to share the images of their creativity projects for which they could choose to remain anonymous or be credited for their creative work.

The main (open-ended) questions centred around:

- *Key Learnings*: (e.g., 'What were your key learnings from doing this Creativity in Action Project? Was it as you expected or were there unexpected learnings for you? How was your experience of making change for sustainability? What did you learn about it through this project?')
- *Impact of the CAP*: (e.g., 'Could you describe your impact (or change) for sustainability through this Creativity in Action Project?')

There was one question which sought the participants' evaluation of the pedagogical elements of the CAP project. It asked them to rate on a scale of 1-5 the extent to which they found the various pedagogical elements useful to (1 = not useful, 5 = extremely useful) and also asked an open-ended question inviting further comments and suggestions.

The other quantitative question asked the students for their reflection on the possibility for the CAP to develop key sustainability competencies (Brundiers et al., 2021; Redman & Wiek, 2021). I had my own theories about what the project might support the development of, but I was curious to see the students' perspectives as they are also professionals, and many of them familiar with the key sustainability competencies through MSLS and/or working in education for sustainability. This question was:

"To what degree to you think the Creativity in Action Project is useful for the development of the following key sustainability competencies (e.g.: knowledge, skills, attitudes)? Please rate from 1 - 5 (1 = not useful, 5 = extremely useful)

And in the question defined the competencies as:

Systems-Thinking: Ability to analyse complex systems and the impacts of sustainability action plans (strategies) and interventions (how they change systems and problems)

1. *Futures-Thinking:* Ability to anticipate future states and dynamics of complex systems and sustainability problems and how sustainability action plans (and strategies) might play out in the future if implemented.
2. *Values-Thinking:* Ability to apply sustainability values, principles, and goals to assess the sustainability of current and/or future states
3. *Strategic-Thinking:* Ability to construct and test viable strategies (action plans) for interventions, transitions, and transformations toward sustainability.
4. *Implementation:* Ability to put into action sustainability strategies and action plans, including implementation, adaptation, transfer and scaling, in effective and efficient ways.
5. *Inter-personal:* Ability to collaborate successfully in inter-disciplinary and professional teams; and to involve diverse stakeholders, in meaningful and effective ways, in advancing sustainability transformations.
6. *Intra-personal:* Ability to avoid personal health challenges and burnout in advancing sustainability transformations through resilience-oriented self-care (awareness and self-regulation).
7. *Integration:* Ability to apply collective problem-solving procedures to complex sustainability problems to develop strategies and successfully implement them, in collaborative and self-caring ways." (Adapted from Redman and Wiek, 2021, p. 6)

Participants were also asked for any further comments or thoughts on their choices in an open-ended format.

As the majority of the data collected was qualitative (open-ended survey responses) the analysis was primarily done using thematic analysis - a method where the researcher can "get a feel for the whole text by living with it" and allows for "intuition and sensing, rather than being bound by hard and fast rules of analysis" (Savin-Baden & Major, 2013, p. 440). This sense-making was first done with initial or open coding – whereby the researcher reads through the data line by line and makes codes or notes in the margin, followed by a second read through of the data with preconceived codes which the data is related to – a version of axial coding (Savin-Baden & Major, 2013). With constant connection of the codes back to the literature themes were developed. A theme is a "unifying or dominant idea in the data and finding themes is the heart of the data analysis process" (Savin-Baden & Major, 2013, p. 427). The themes that were identified in this study are presented in the Results and Discussion section.

3. Results and Discussion

In this section some reflections on the course as a whole are presented, followed by a description of the key learnings that the students identified through their survey responses. After this will follow a discussion and

CAP; and finally, recommendations for educators interested in applying the CAP in their own context. Direct quotes from participants are used to better illustrate findings in this study and are represented in italics and quotation marks.

Reflections from participants on the project were extremely positive. The final question in the survey asked for any other reflections not shared already, and the vast majority of them said variations of *"thank you",* and that this project gave them the *"mandate"* to do or complete something they had wanted to do but would not have otherwise taken the time. One response: *"This was my favourite project of the year. I loved it so much. I learnt so much"* and another who had struggled with the project along the way, described how life changing the CAP was for her, discovering the many ways to approach sustainability that were more creative than her current life path: *"I have started studying something new and completely different... thank you for helping me on this path!"* Some described the challenges of doing the project – of stretching their comfort zones – and some had suggestions for improvements for future iterations. These will be discussed further below.

3.1 Themes of Key Learnings through the CAP

The key learnings identified by participants through the CAP can be summed up in four themes:

- *Communication* - the value of artistic and creative expressions to communicate sustainability, and that communication is two-way (speaking and listening)
- *Concrete* - the empowerment of 'being embodied' and creating something 'concrete'
- *Courage* - the challenge of expanding comfort zones and the courage that requires
- *Creative thinking* - the revelation of how many creative ways sustainability issues can be tackled.

The benefit of creativity and the arts in improving communication for sustainability was mentioned by many respondents. Some described how they felt understood by others in ways they had not before: *"others around me seemed to understand me and my vision more clearly"* and *"I learnt that making change for sustainability can be effectively achieved through creative means and sometimes it can be more impactful or it can resonate with a broader population than technical or academic language/theory".* One suggested that *"...arts are a powerful language that speaks directly to the heart,*
not being so questioned by the rational mind". Another responded that they learnt to talk about this dark and difficult topic of sustainability through engaging humour and laughter through in stand-up comedy training *"...made me think a lot of how to talk about something that you love and believe in a different way".* Communication is of course two-way. There were other students who realized through the CAP of their need to listen more to others in their communication, to understand the perspective of others who they were hoping to influence and relax *"... like I never relaxed in my life and abandon completely the selfish hope to change a system the way I want it",* to invite others in, and this realization *"changed me a lot in terms of how I approach my change-maker role in the world".* Communication at its best requires the mouth and the ears, and of course only existing in relationship. The ability to both speak in mediums or *"languages"*

create a sustainable future are qualities much needed in us all.

Many students used the word *"concrete"* to describe their key learnings through the CAP and how *"grounding"* it was to be *"... using my hands, moving my body and using my creativity in something more concrete and tangible..."*, and *"...I believe these activities will support me doing my sustainability consultant work"*. Another described it as empowering *"... to see concretely things emerging that I have created myself. I felt my potentials as a human being/sustainability leader got nurtured"*. The creation of something real and tangible in the world – a product – was a *"mandate"* through the assignment, but the realization of many students was around the intangible benefits and learnings of engaging in the process of creating a thing, and the application of this into their everyday lives and work.

There are challenges of inviting students to stretch their comfort zones and engage in creativity and the arts and this requires courage. It became obvious that many have had bad experiences with this in the past – for example of being told by art teachers that they were not good at art or judged on the product, not encouraged in the process of creating. Others spoke of *"not being particularly creative"* and or not knowing where or how to start. In the class sessions, the one-on-one coaching sessions, in the CAP assignment description, the focus was on process, on expanding comfort zones with a playful attitude of trying something you have always wanted to, encouraging students to "stretch yourself towards new ways of thinking, being and doing rather than producing an intervention or creative work of the utmost 'quality', 'beauty' or 'success'". Many mentioned the fact that assigning the project as a requirement was a way for them to push beyond their inhibitions, and then the realization that *"creativity does not have to be perfect or good, it is just about starting it"*. The lessons and the benefits of doing the work then opened up, mainly that there are many creative ways to tackle sustainability. Courage is an essential quality for sustainability change agents (Ayers, Missimer, & Bryant, n.d.; Mouritz et al., 2022), and 'building this muscle' through the CAP is an additional benefit.

Creative thinking about sustainability challenges is an essential quality moving forward (Newman- Storen, 2014; Patton, 2018). For many students an outcome of the CAP was the realization of the variety of ways that they can address sustainability challenges in their lives and work. One student said:
"By the end of the course, not only was I able to see the possibility of approaching sustainability in a different way as I was doing it, but also I saw the great potential for impact that a creative intervention can have when it is set in the direction of sustainability efforts. And at a personal level but connected to what I was saying before the course broadened my perspective of what a creative endeavor is."
The CAP provided an opportunity to practice creativity and think creatively, expand their comfort zones though building courage, and produce a concrete intervention in their lives for sustainability.

3.2 The Creativity Projects and their Impact

There was a large variety of initiatives undertaken through the CAP, and the sheer diversity of approaches to solving sustainability challenges creatively was inspiring for many. To quote one survey participant the course " made me see the possibility of approaching sustainability from other fields

children, roommates, workplaces and neighbourhood and/or online communities. Examples of some of the projects include:

- Making seasonal decorations with the family from things that come from nature and can go back to nature, reducing waste and increasing connection to and time spent out in nature (instead of buying them from the shops, often made far away and in plastic)
- Crafting a compost bin out of recycled wood with the children in the hopes of teaching the family a *"new normality"* in which *". waste is a human concept and doesn't exist in nature and shouldn't exist in society"*
- Drawing and painting an image of an alternative future vison for an international environmentally and socially sustainable tourism facility in Zambia's with this as a main economic force as opposed to the destructive copper mining that currently exists
- Making handmade soaps and giving them away as presents with a sustainability message: "not having to buy plastic, knowing what is in it and not having micro plastics"
- Cooking a *"Carrot Greens Pesto"* dinner for a group of diverse friends and discussing cultural differences around which parts of the vegetables you can eat, buying vegetables in plastic, and ways to reduce food waste.

The images below showcase some of the projects. Figure 1 demonstrates the reuse of old clothes to give life to them with the hope to inspire others to make children's clothes out of ones that are old and broken. Figure 2 shows a children's book co-created with the family in an attempt to communicate what can be very complex sustainability concepts to children, with the hope of publishing the book and thus increasing its impact. Figure 3 shows a neighborhood engagement installation inspired by the story of the Hummingbird which does its part to put out a fire... or, make its world a little bit better. This project invited others in, to reflect and share, their hopes and *"fires"* as well as bringing beauty to some particularly *"ugly and dirty parts of the neighbourhood".* Figure 4 presents a CAP using non-fungible tokens (NFTs) to register images of nature. This student was curious to learn more about *"blockchain technology, decentralized finances, gamification and how we can hack this future tech world and use it for creating more positive impact for a more sustainable and just society*". The aim was to hack this new technology and connect people to nature this becoming more conscious of it and how it is constantly transforming before our eyes.

Figure 2. *Children's Book '1,2,3 Yeah for Sustainability!' co-created with family (A. Jannink)*

Figure 3*. 'We can all be Hummingbirds' a neighbourhood engagement and visioning installation by Carlotta Cataldi.*

Figure 4. *Nature Collection NFTs by Telma Gomes.*

In describing the impact many of the students answered that what they had done was *"not enough"* or that they had hoped to have made more impact for sustainability on more people. One participant said: *"I am unsure if I actually made much of a change but sometimes you can only see the effect of that later on".* But many of them also talked about the *"little seeds planted"* by their work, that it felt like a beginning of something new and their desire now to do more.

3.3 Key Sustainability Competencies and the CAP

Much academic literature has described and defined the Key Sustainability Competencies desirable for sustainability graduates and the most recent and well known and cited work describes 8 competencies (Brundiers et al., 2021; Redman & Wiek, 2021, 2021) which are articulated previously in the Methods section. In designing this project an intention held by the staff was to encourage the students to "go out and make change in the world". An assumption I held was that students would find it beneficial support for Implementation competence – the ability to put into action sustainability strategies and action plans, including implementation, adaptation, transfer and scaling, in effective and efficient ways. The results which can be seen in Figure 5 show that most students did find the CAP supported the development of this competence, and indeed all the competences but particularly that the CAP assignment supported the development of their Intra-personal competence – one of the newer identified competences which speaks to the ability to avoid personal health challenges and burnout in advancing sustainability transitions; and Values thinking competence.

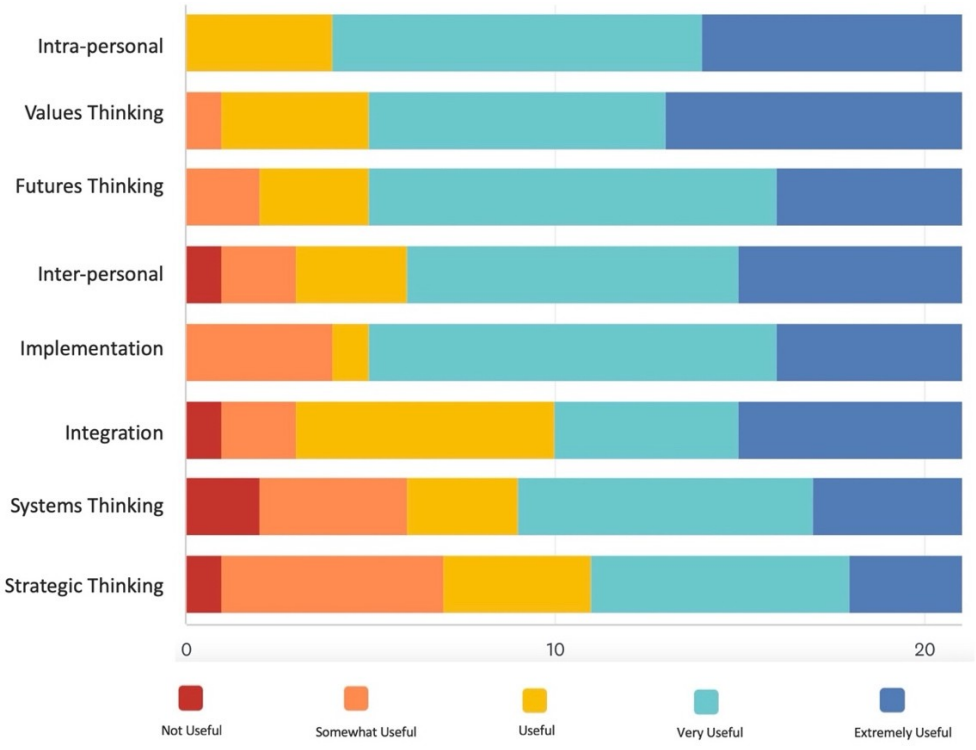

Figure 5. *The Creativity in Action Project's Support in Developing Key Sustainability Competencies According to Respondents.*

All 21 indicated they thought the CAP was "Useful", "Very Useful", or "Extremely Useful" to support development of the Intra-personal competence. As one of the 'newest' Key Sustainability Competencies, researchers still grapple with what the Intra-personal competence actually consists of (Brundiers et al., 2021; Redman & Wiek, 2021). A recent paper currently under review by Ayers, Missimer and Bryant called "The Dark Matter of Sustainability Leadership—Intrapersonal Competence for Sustainability" describes in more detail what these may be. Many of the key learnings identified by participants in the CAP are similar e.g.: Courage, flexibility and open-mindedness, the ability to let go, humility, to honour diverse perspectives, to cultivate optimism and hope are all elements represented in both, suggesting that the CAP is a useful pedagogy to support Intra-personal Competence development.

Values thinking is the ability to apply sustainability values, principles, and goals to assess the sustainability of current and/or future states, and is suggested by some as a pre-curser to all the other sustainability competencies (Brundiers et al., 2021). One participant's quote describes this exactly: *"developing a creative project that is out of your comfort zone, contributes a great deal to knowing ourselves, knowing the values we hold, what we care about, what moves our hearts and inspires us.*
This clarity can then be expressed in many activities or tasks that we do within the sustainability realm (strategies, planning, connecting to others, etc.)". Figure 5 shows respondents also see the CAP as a supportive pedagogy to develop this competence also.

Brundiers et al. (2021) suggest learning objectives for educators to use that can support the development of the Key Sustainability Competencies. The results, impact and feedback of the participants in this study

into scientific inquiry to counter the positivistic perception that values are outside of science. Achieving this desired learning objective to develop the values thinking competence can be seen in the CAP, with the integration of values into creatively solving sustainability problems. This can be seen from the results in Figure 5, and some of the quotes from the participants that have already been shared, who discuss the realization that they needed to clarify their own values, as well as engage with and listen to others to create a more sustainable world (in particular, see the section 3.1 above on Communication). A further learning objective that is recommended is that sustainability is a solution- oriented field, and that it must be done with stakeholder engagement (Brundiers et al., 2021). The CAP scaffolds the learning of both of these objectives as it requires students to initiate a creative solution to a sustainability problem in their own lives and world. Although not essential to engage others in the creative process, the intended impact is on creative change on others. A learning for many through doing this project was of the need to invite others into the project or process, as the realization that the "*selfish hope to change a system the way I want it"* is not the way to make change in the world and was the inspiration for the beautiful community engagement 'We can all be Hummingbirds' creativity project.

Results indicate that the CAP was experienced by most of the students as a useful assignment to develop the Key Sustainability Competencies, but it will of course depend on how people approach the project. As some students reflected, if the intention is to build these competencies, then framing the CAP with these in mind would allow the students to craft their projects accordingly.

3.4 Pedagogical Elements of the CAP

The feedback from the students suggests that doing the project, sharing the project with others and witnessing their projects were the most important parts for most respondents. Figure 6 outlines the responses in the order of the elements of the delivery of the CAP.

The main two recommendations for future iterations of the CAP are to have a more ongoing presence of the project throughout the year and to have "Creativity Coaching Buddies". The course was year long (Jan 2021 – Jan 2022). The CAP was introduced at the beginning of the course through an introduction video, and the webpage. There were two 2-hour class sessions focussing on the CAP in March and September 2021. The option to complete and submit the CAP was available the whole year, however there was only one final Showcase/Exhibition Event (online) which was at the end of the year coinciding with the due date for the CAP. This was mainly due to staff availability, and the fact that the project was a small part (2.5 credits) of a larger course (15 credits). One suggestion to provide a more ongoing presence of the CAP might be to have a mid-year Exhibition event where half or some students present. The class could be split into *"batches",* one at the midway point and one at the end. Alternatively, prototypes could be shared at various points along the year. Making sure to remind students of the CAP in every online session (these happened once every fortnight) would also help.

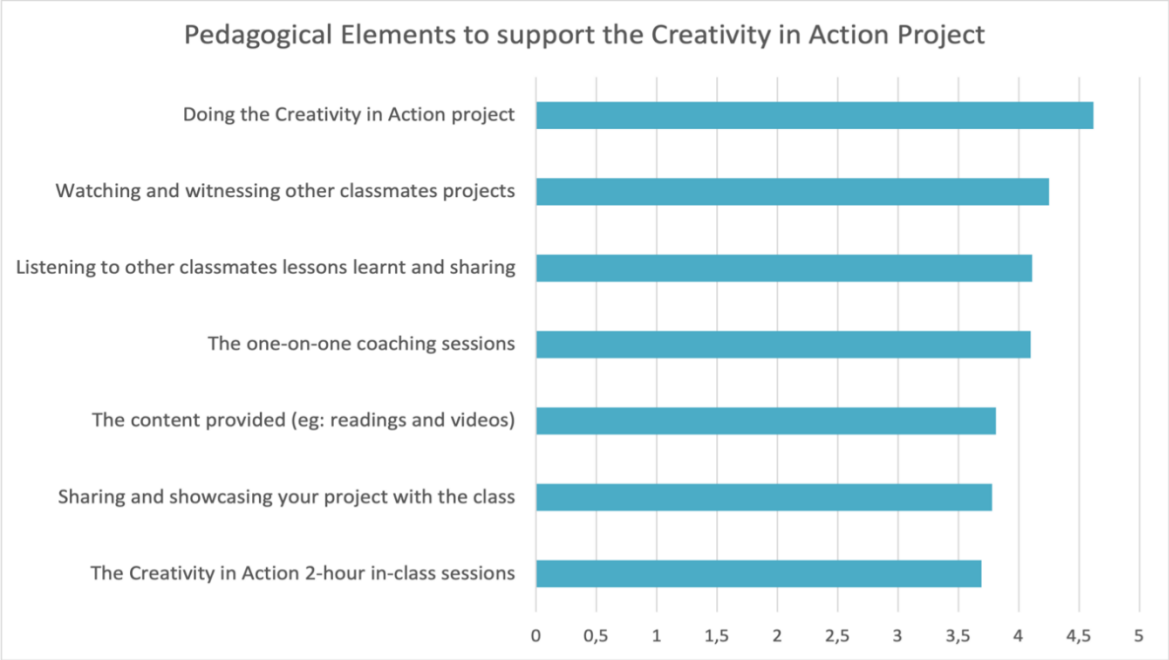

***Figure 6**. Pedagogical Elements to support student learning in the Creativity in Action Project and their 'usefulness'.*

The *"Creativity Coaching Buddies"* or peer support structure is another way to help students keep each other motivated and moving towards something that for many will stretch them out of their comfort zones and require courage. As many expressed finding inspiration and learning from witnessing each other present their projects this sharing of those earlier in the year could help inspire those still stuck on what to do. As the key learning is doing the project this might also support students who may not have made it to the end of the course and complete the CAP in case this was a factor in them not completing the course.

This study looks at the CAP within a distance learning course, and it is worth noting that in the course which provided the inspiration is taught both face-to-face and online suggesting the pedagogy can be adapted to distance, face-to-face or hybrid settings (see: Mouritz et al., 2022; Newman-Storen, 2014).

3.5 For Educators of Sustainability

Creativity and sustainability as essentials for global and economic survival and for individual wellbeing (Jones, 2013) and the future of higher education requires educators across all disciplines to develop capacity in teaching sustainability ('DECODE Sustainability – European Deans Council for Sustainable Development', n.d.; GUNi Network, 2022). This paper presents a creativity-based assignment as a valuable pedagogy for educators for sustainability. The CAP is an assignment that could be used in many fields and disciplines with simple elements. From personal experience I can say that it is a pedagogy that can be used even if you don't identify or feel 'creative' yourself. Two students implemented a similar project for their own students to do which gave them courage to do more themselves! One responded that when watching their students in Russia and *"how brave they were"* in their

project as a chance to do something that you maybe would never do..." the teacher's courage grew. Thinking and literature around creativity proposes that the product must be something of value (Wreen, 2015) which brings up the questions of value to whom and evaluated by whom? This paper argues that the experience of engaging in creative work provides impact and benefits in both the inner and outer realm that are impossible to measure, and the process and press of challenging oneself to step outside one's comfort zone and 'get creative' can be the gift in and of itself.

4. Conclusions

Education is seen as a key leverage point to shift society towards sustainability transformations however as with sustainability approaches in general, the potential of creativity and the arts remains untapped as a tool, topic, process, pedagogy and way of thinking in ESD. This paper presents a creativity-based assignment as a valuable pedagogy for educators, and findings demonstrate realization of the students of the value of creative expressions as a tool for communicating sustainability; the empowerment of creating something 'concrete' and tangible; the courage of expanding comfort zones and the benefits of doing so; and the practice of creative thinking and the revelation of how many creative ways sustainability issues can be tackled. Descriptions and images of the projects are shared to provide concrete examples for inspiration and future iterations. The potential value of the CAP to build key sustainability competencies – particularly the newly identified Intra-personal competence is discussed. The intention of this study is to provide educators and learning designers with inspiration and a practical, adaptable, and impactful pedagogy for the development of sustainability leadership that could be used and adapted to various contexts and recommendations for educators interested in applying the CAP in their own context. It is hoped this will in turn support societal transition towards sustainability through empowering students to be sustainability change agents by applying their creativity to solve a sustainability challenge in real life.

Developing Social Sustainability with Circus-based Methods

Emma Stenström[1], Andreas Skjönberg[2],

[1]*Stockholm School of Economics, emma.stenstrom@hhs.se*
[2]*Hyper Island, andreas.skjonberg@hyperisland.se*

Abstract

Can circus-based methods develop trust between people in organizations? If so, how? This paper reports the results of a one-year-long research project in collaboration with the Swedish circus company Cirkus Cirkör, the Center for Arts, Business, and Culture at the Stockholm School of Economics Institute Research, and the educational organization Hyper Island.

The project aimed to explore if circus-based methods could be used to develop trust between people in different environments. Different methods were already in use, and new methods were invented in several interdisciplinary laboratories. Special attention was given to developing digital methods due to the pandemic. The result was a series of performance workshops.

As a next step, the performance workshops were tested in five different environments, covering various sectors: a government agency, a private corporation, higher education, a municipality, and a not-for-profit organization.

Interviews and surveys were conducted in all these different environments, and at the university, randomized control groups were used to measure and compare the effects.

The results are fascinating. Circus-based methods and performance workshops add imagination and creativity, hope and surprise, embodiment and entertainment. They can contribute to increasing trust and extending the mind. We conclude that the experiences indicate that trust can be fostered in the short term. Increased trust can potentially enhance social cohesion and sustainability.

Trust is experienced in different dimensions: physical, emotional, interpersonal, self-trust, cognitive- and affect-based. Circus becomes a method, a metaphor, and a mindset, an area of projection and enchantment. The performance workshops allow for embodied learning.

Previous studies have emphasized the psychological skills that can be enhanced: the ability to learn from failures, collaboration, vulnerability, focus, and attention, but we can also see the philosophical aspects. These kinds of circus-based performance workshops can shift how we relate to the world, create new horizons of knowledge, build communities, and, potentially, cultivate social change.

The project addresses several goals and targets. In general, it is goal 16 that is of particular interest. The paper builds on several theoretical strands, particularly circus-based methods and trust and quantitative and qualitative methods.

Keywords: Circus-based methods, Trust, Embodied learning, Resonance

1. Introduction

Trust is a topic that has been studied from a multitude of perspectives, including sociology, philosophy, economics, psychology, management, international relations, automation & computing, to name only a few. Most definitions revolve around expectations in a relationship (James, 2005; Mayer et al., 1995; Kydd, 2005; Rotter, 1980). According to Luhmann (2014), trust reduces the complexity of social systems, which is needed for people to function efficiently despite a very high amount of information regarding social cues and risks regarding personal stakes.

In this paper, trust is defined as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other party will perform a particular action necessary to the trustor, irrespective of the ability to monitor or control the party" (Mayer et al., 1995, p 712). According to the authors, trust has a complex foundation and is not to be regarded solely as an emotional state or tendency.

Trust is also a prerequisite for societies to function well in general. Robert Putnam (2000) wrote: "A society that relies on generalized reciprocity is more efficient than a distrustful society because money is more efficient than barter. Honesty and trust lubricate the inevitable frictions of social life (p. 135)." This is also the case within organizations. In Sweden, "trust- based governance" is proposed as the alternative to "new public management" in the public sector (Bringselius, 2017). Instead of relying on measurement and control, trust and judgment become cornerstones in this philosophy.

Trust is one of the critical capabilities and skills that must be developed on an individual, collective, and system level (Wamsler et al., 2020). Further, trust is linked to sustainability. It is a critical component in creating social cohesion, and social sustainability is essential to reaching the global goals for sustainable development, 2020).

Some argue that trust might be on the decline. The global communication firm Edelman has studied trust for over 20 years. Their latest publication, "Edelman Trust Barometer 2022," claims that the "world is ensnared in a vicious cycle of distrust, fueled by a growing lack of faith in media and government." A growing crisis of trust in governments and institutions is also supported by, among many, the World Economic Forum (Mantashyan, 2022) and the United Nations Department of Economic and Social Affairs (Perry, 2022). Flew (2019) argues that "the rise of populism worldwide can be seen as arising from a more general crisis of trust in social institutions" (p. 1).

In circus training, trust is a crucial factor. Several studies show the critical role of trust, how trust is one of the qualities often developed through circus training, and how that, in turn, can enhance social cohesion (Dubois et al., 2014). The pedagogical effectiveness is not limited to specific techniques but includes the development of an array of personal and social capabilities. Essential among these is the ability of participants to trust themselves and others (Bessone, 2017).

According to several scholars, participants will develop an array of personal, interpersonal, and social skills." Chief among these skills is that of trust: trusting oneself and trusting others are vital components of the personal, interpersonal and social skills that develop through the practice" (Cadwell, 2018, p 24).

Circus has a long tradition of working with communities and training non-professionals in basic circus skills. There is a growing body of research on using those circus-based methods outside the artistic practice. Many studies focus on youth or social circuses. A social circus is a" form of non-professional circus education where the focus is on personal development, social inclusion and self-expression as opposed to the achievement of a high level of artistic technique" (Cadwell, 2018, p 22).

The findings from these studies can be used to help interpret our results, but we also notice a gap. Few studies focus on how circus-based methods can be used in settings other than among youth and underprivileged groups. This paper explores the effects of circus-based methods on organizational and professional development, particularly on trust and sustainability.

2. Research Process

For the research process, design thinking principles have been used. The process was divided into four phases.

The first phase identified current challenges in different workplaces through interviews and a literature review.

In the second phase, the focus was turned toward the circus practice. Qualitative interviews were conducted with circus artists and circus pedagogues. A semi-structured discussion guide was set up, which

(Britten, 95; Potter & Hepburn, 2005). The data from the qualitative interviews were analyzed through thematic analysis by systematically identifying, organizing, and clustering patterns of meaning (themes) across the data set. Additional interviews were conducted with organizations that have used circus-based methods and an invention of methods that circus artists had used.

Insights from the research were then processed in a series of co-creation sessions, with the working group containing artists, pedagogues, an administrator from the circus, representatives from education, foreign affairs, and a corporate organization. These workshops were held iteratively throughout the process. The outcomes were mainly physical exercises on developing trust and creating performance workshops for different settings.

The fourth and final step was the workshops conducted in a series of iterations between November 19, 2021, and May 8, 2022. After each workshop iteration, participants' feedback was captured in qualitative and quantitative data. The data were analyzed in the following co- creation workshops with the working group and concerning theories. 190 people participated in five settings: a government agency, a private corporation, an educational institution, a municipality, and a not-for-profit organization. The aim was not to compare the different settings but to test the workshop in different environments. In the educational background, a randomized control group was used so that half of the students participated in the circus workshop and half in a more ordinary cognitive-based seminar on trust, addressing the same topics, but not through circus-based methods.

Ethics

All participants were asked to sign a consent form where they agreed for the authors to use their input following these critical regulations:

- All data were to be anonymized
- All were asked to read and agree to a privacy note
- All were informed that they have the right to change their mind about what the author does with their information and to withdraw from the research entirely at any point and for any reason.

Table 1: Research process

First step: Understanding the Problem	Second step: Discover	Third step: Define	Fourth step: Develop & Analyze
Aim			
To understand the problem, primary research was conducted together with a literature review.	To understand what makes trust building in circus an integrated part of working together, primary research was conducted with respondents who have 'circus' as their profession or have had connections to the circus in their professions.	To create solutions to build trust, insights from interviews, literature reviews, and workshops were integrated into a series of co-creation workshops.	To understand the solution's potential, shortcomings, and areas for further development, a series of workshops were developed and tested in iterative sessions with different target groups. Quantitative and qualitative surveys were conducted with all external participants in order to explore how trust can be created through circus-based methods.
Method			
Qualitative Interviews & Literature Review	Qualitative Interviews	Co-Creation Workshops	Online and Physical Workshops Quantitative & Qualitative Surveys
Number of participants			
N=14	N=16	N=14	N= 190
Guiding Focus Areas and Participants			
Challenges to trust in a business context: • 6 employees on different levels Challenges to trust on a societal level: • 8 local employees at embassies across Europe	Insights on the process of trust among circus acrobats: • 7 acrobats. All working professionally for more than 4 years Gather already developed methods for trust: • 4 circus pedagogues. All with at least 5 years' experience as pedagogues and some professional experience working as performing artists Understanding what makes the circus methods and its approach unique to actors from other fields: • 5 people who are working in organizations, municipalities and companies who have used circus in workshops	Assuring a circus perspective: • 4 circus pedagogues • 3 circus artists • 1 CC employee Assuring relevance to other fields: • 2 participants from the Swedish Ministry for Foreign Affairs • 2 participants from the agency Futurniture Facilitation and transfer of knowledge: • 2 members of the core group	From a government agency: • 10 participants from the Swedish Ministry for Foreign Affairs From business: • 82 participants from Allianz, a mix of team members and managers From education: • 68 participants from a global master program at Stockholm School of Economics From a municipality: • 22 participants from the municipality of Malmö in Sweden From a non-profit organization: • 8 participants from a community sewing atelier which offers educational opportunities to tailors with refugee backgrounds.

3. Results and Discussion

From the first iteration, with participants working in a government agency, there were indications of the workshops' ability to transfer the circus' approach to trust in a playful setting and through embodied learning. The potential was identified for examples from the circus to work as a projection tool for the participants to discuss sensitive topics often not addressed with colleagues. Especially the circus approach to failure, as an acknowledged part of the creation process, served as an effective tool for a mind shift in the perception of failure.

Several iterations were then conducted at the company Allianz Suisse. During these iterations, perceptions of personal connection, level of trust, and readiness to share concerning the other participants before and after the workshop were gathered.

and personal connection among the participants.

- 85.7% of the participants either agree or strongly agree with the statement that the workshop increased their trust in the other participants.
- 85.6% of the participants either agree or strongly agree with the statement that the workshop increased their readiness to express themselves more openly with the other participants.

The qualitative feedback indicates that the Circus' perspective on trust and collaboration served as the basis for discussions among colleagues.

Two workshops were carried out with master's students at the Stockholm School of Economics. Half the students were randomly assigned to an online circus workshop, and the other half to a cognitive, more traditional workshop. All students answered a survey before and after the workshops to measure if a sense of trust was increased.

Also, here the findings were validated.

- 69.4% either somewhat agree or strongly agree with the statement that the circus workshop increased their trust in the other participants.
- 57.3% either somewhat agree or strongly agree that the circus workshop increased their readiness to express themselves more openly with the other participants.

However, and this is important to notice, the other non-circus workshop received similar ratings, which indicates that development could also be a critical topic. When assessing the qualitative feedback, the circus' methods and approaches are perceived to give new learnings regarding trust. The last workshops have not been evaluated yet. Therefore we only have the (very positive) qualitative feedback to rely upon, not the quantitative. To sum up, most of the participants in the performance workshops experienced an increased trust in the other participants.

Therefore, it seems like circus-based methods can increase the experience of trust. We discuss how in the following, using theories from previous studies of circus-based methods and trust.

Through an iterative, interdisciplinary process, we created performance workshops using circus as a method, a metaphor, and a mindset. Circus training can enhance trust-building in a physical, embodied way, for example, when participants collaborate and guide each other blindfolded. An example is a participant who said:

"The "blind" test and trusting the other to direct your way made the most impression on me."

Previous studies have also shown that training circus skills can change the modes of encountering others, fostering trust, collaboration, bodily knowledge, and interactions (Bolton 2004; Dubois et al. 2014; Spiegel et al. 2014; Wilson 2016).

solid and authentic and act as successful accelerators for authentic discussions among the participants. As a metaphor, the circus becomes an area for projection. A natural connection between trust and circus acrobats creates curiosity for the participants to engage in the workshop. Here is a voice from a participating student:

"Focusing on a non-business area and projecting it into our studies made the most impression on me.

Previous studies support this. Several scholars emphasize the "enchantment" element connected with the circus. Enchantment is" a state that embraces the potential to become otherwise" (Wilson 2016, p 2). Circus is a sort of 'enchantment' and surprise, unveiling meaning in" new forms of attachment to the world" (Bessone, 2017, p 656).

As a mindset, the participants picked up many different things from the circus: the importance of trust, learning from failures, deliberate practice, playfulness, etcetera. These could be transferred to their settings, or as one participant expressed it:

"Working together (well) is about collaboration, practice, practice. Practice and patience. More playfulness would be very good also in a formal context as you actually "perform" better because you have fun and try out new things."

Circus teaches participants 'that nothing is impossible, and that doubt and fear are to be examined and absorbed into positive action' (Bolton, 2004, p. 193). Circus techniques and performances can be used as resources for interpersonal trust instead of achieving a high level of artistic technique (Cadwell, 2018). The aim is to create a space 'where ideas can be shared without fear, opinions, and attitudes can be openly stated, and fruitful conversation can flourish and grow' (Bolton, 2004, p 204).

Digging deeper into the topic of trust, previous studies of circus training have noted that trust is developed physically and emotionally between each other and oneself. Even if it is not a risk to life, losing face is seen as a threat – and needs trust. Participants had to trust each other physically and emotionally - and trust themselves. One expressed it:

"Yes, I experienced trust in the sense that because they would make fun of me or judge me while balancing badly. ;) So I felt very comfortable and therefore trusted myself."

Trusting those around you and trusting in the safety of the situation is crucial, but until trust in

t. Still, until you take that first step, the participants cannot truly participate. There genuinely trust becomes about trusting oneself, trusting others, and others, and as several scholars have pointed out how circus training can enhance psychological skills in participants, for example:

"Results showed that mental skills such as confidence, concentration, energy management, and emotional management are considered integral to success in circus also reflected differences that exist between sports domains, such ability to embody emotions and connect with the audience." (Ross & Shapiro, 2017).

Others emphasize the ability to focus. "Circus is a continuous dialogue with the audience and the viewers need to feel that the performer is "in the moment". Indeed, that ability to remain focused while allocating

movement sciences and sports psychology. (Filho et al., 2016). Attention was also a key feature in an earlier study we conducted on what circus training could bring to business students (Stenström, 2016).

Other psychological benefits include the ability to relate to others (Cadwell, 2018) and a reduction in emotional problems such as worry, nervousness, lack of confidence, and fearfulness. (Neave et al., 2020). Welby Altidor, former Executive Creative Director of Creations at Cirque du Soleil, further describes how circus skills can enhance creativity and courage (Altidor, 2017).

Circus builds on risk as a key component. Without something to risk, the trust would not be needed (Coleman, 1990; Deutsch, 1958; Jøsang and Presti, 2004; Molm, Takahashi & Peterson, 2000; Szerszynski, 1999). The link between risk and trust becomes even clearer through Robbins' (2016) reasoning that trust emerges under conditions of risk and uncertainty – conditions in which the outcome of matter 'Y' is unknown. Thus, risk and uncertainty are necessary conditions for trust. Or, to rephrase it, trust is a way to calculate how to deal with uncertainty and risk logically.

Risk in the circus plays a central part in the performance of the act, the performed danger, as performative risk. The audience's perceived risk in the performed circus act is what draws an audience to be amazed by "death-defying" acts.

Circus also has a history of embracing failures and learning from them. Ibañez (2018) argues that trying out something new offers us opportunities for growth and change, "but with those opportunities comes the risk of failure. While we intellectually understand that to grow, we must take chances and try things we cannot accomplish until the skill has been learned, it doesn't seem to help how we feel about failing." Failure can offer an opportunity for building trust through vulnerability when acknowledging failure. Failures also provide chances for development and learning new things if you learn from your mistakes. As two participants noted, independently:

"I was reminded that failure is necessary and good."

"Failure should be celebrated, as it offers the opportunity for something new."

The approach to failure in the circus plays a central role in trust building. Between acrobats, failure is the very start of each new learning curve. When an acrobat starts training a new trick with a partner or alone, failure is assumed. The process has similarities with reward-based learning (Palminteri et al., 2015), as, among acrobats, the failure is acknowledged and owned, thus not an indication of a breach of trust. This enables a more accurate reflection detached from the influences of emotions. Using this circus approach in training did not only support a mind shift regarding failure but also as an enabler for vulnerable and authentic conversations.

These conversations contributed to perceived reliability among the participants and fostered sustainable relationships built on interpersonal trust.

The notion of choosing trust as a mindset made an impact and the circus perspective on failure. One

"What I take from the workshop is to give initial trust instead of being suspicious. Take a leap of faith, communicate, express doubts, and collaborate on the best solution together".

Among acrobats, acknowledging the failure, analyzing it, owning it, taking responsibility, and showing a change in the next training session builds trust. When acrobats examine the loss in several small steps, each involved party learns how the other(s) behave in situations of danger and stress. And, through the event of failure, each party learns about the other's (and own's) ability, benevolence, and integrity, resonating with Mayer, Davis & Schoorman's model (1995).

Faith in judgment and competence is also built by affect-based- and cognition-based trust elements. Affect-based trust plays a significant role as a starting point as the connection between the acrobats needs to be personal and authentic to withstand the challenges of training, failure, pain, and exhaustion. The characteristics of affect-based trust resonate with other researchers' findings (Lewicki & Bunker, 1995), involving individuals creating a common ground by understanding expectations on responsibilities. When affect-based trust is established, cognitive-based trust plays a prominent role. When there is a high stake (life or death/injury) investment, a person's actions play a more prominent role than the emotional connection.

A significant discussion in the co-creation workshops was what characterizes the circus, or as it was expressed:

"How do you "circusfy" a workshop?"

Is it the skills that characterize the circus? The objects? The aesthetics? The ethics? The attitude? Or, perhaps, a combination of all and more.

From the outside, an essential element was the instructors, who all came from the circus and acted as role models, showcasing the circus mindset. Capturing this circus mindset is not easy, but it has elements of an inclusive attitude, creativity, presence, physical intelligence, humor, surprises, social awareness, and care. During the co-creation workshops, it was, for example, often pointed out how important it is that everyone can participate and that nobody feels too uncomfortable or excluded.

In earlier studies, the role of the instructors has been pointed out. "The presence of soft skills among circus tutors essentially goes unnoticed. Much like plumbing, it only becomes a problem when it stops working. However, when a tutor lacks that ability, or when insufficient time is given to trust-building within the class setting, the efficacy of circus as a strategy for personal development falters." (Cadwell, 2018, p 28).

Another aspect that turned out to be important in co-creation was the space. After a few iterations, one of the artists came up with the idea to build boxes showing the different topics in the workshop: trust, failure, collaboration, etc. These boxes could then be used in different ways: to play with, to co-create a workshop around, to introduce oneself, to build a physical space, etc. The boxes created an experience and made the circus element stronger.

Space is also vital in a metaphorical sense. The space blocks everyday life out of the 'circus bubble.' It

educational or business settings – towards the 'new' rules and goals of the game. This opens opportunities for new experiences, perspectives, and relationships.

Space is not only physical but also emotional. The principles of the circus inspire a space where ideas, opinions, and attitudes can be openly stated, and fruitful conversation can flourish and grow, according to Bolton (2004). This was also incorporated in the performance workshops, where attention was given to designing workshops where participants would feel safe. Just like a trapeze artist need to ensure that the trapeze and crash mat is functional for them to feel secure enough to train, it is essential to assure that all participants are familiar with the used technology and the anchor points. It is necessary to set a transparent frame for open and honest conversations.

Objects, and the manipulation of objects, are other key features of the circus. According to research, incorporating objects can be one way to extend the mind (Paul Murphy, 2021). The workshops included everyday objects, apart from boxes, plastic bags or newspapers, feathers, and balls.

Others include movement and the body (Paul Murphy, 2021), which might be the most apparent element when using circus-based methods. "It is the physicalities, and corporeal relationship experienced rather than the narratives illustrated [in the creation process] that become the locus of transformation' (Spiegel, 2016, p 55). Those comparing circus with sports emphasize how circus arts are non-competitive and open up physical experiences for those who do not like to compete (Ross & Shapiro, 2017). Embodied learning is a crucial feature of circus training. Or, as one of the participants writes:

"I've learned a new thing, played, and had fun. I felt my body. Experienced focus (inner and out)."

This is in alignment with the sociologist Hartmut Rosa's concept of resonance. Circus art can support the participants' experiences of resonance, which in turn can help them restore their relationship with the world. Instead of appropriating the world, as is often taught in management education, art opens up for *experiencing* it in an unpredictable, uncontrollable way. The experience is embodied through the skin, breath, voice, gaze, and other bodily organs and senses (Rosa, 2019).

Many studies have observed the psychological effects of circus training, but as important are the philosophical ones of changing the relationship and becoming more responsive to the world. "Undermining bodily and emotional labeling and expanding empathy, the social circus has the potential to affect subjectivities and communities beyond the time and space of the workshop, to foster an 'ethics of becoming "more responsive" to the world' (Wilson 2016: 10).

The specificities of the circus foster" a challenge to habitual modes of relating, one that breaks with habits of thought and interaction, to open up new individual and collective horizons for future social and cultural development" (Spiegel 2016, p 64).

This is true for bringing in arts-based methods in general. Art can be used as a sensitizing experience, bringing unexplored bodily senses such as tactile and taste to the educational setting (cf. Küpers 2017, Gallos 2020). Artistic interventions, such as our circus workshops, can help to destabilize the participants' bodily positions and provide them with a sanctuary in the form of an alternative discourse or a new vista

Bessone (2017) shows, for example, how circus training enhances the opportunities to be surprised by 'others' and encounter them in ways that undermine reductive representations, and Wilson (2016) continues: "Emphasis on creativity also implies accepting failure and ambivalence, remaining attentive to unknown outcomes and unpredictable solutions – that is, working towards an 'ethics of attunement'" (Wilson 2016: 15). This is in line with Hartmut Rosa's idea of resonance. One participant expressed:

"The circus interlude was simply "refreshing" and "something different": in other words: "Sau gut ;-)." The topic "trust" is so enormously important, and also every partnership/marriage/etc. is based on trust. This feeling of trust releases enormous energies: you feel protected, sheltered, supported, and caught if something does not work out as desired".

An earlier study explores how circus skills can be integrated into academic subjects. The authors conclude that "three common ways students experience agency through the integration of circus practice and academic knowledge. First, students can build new knowledge from their domains of comfort into domains of discomfort. Second, combining embodied and academic knowledge expands student access to creative solutions, thereby expanding their knowledge horizons. Third, we notice that the collaboration inherent in the practice of circus arts enables community building, which, in turn, elicits the development of trust in new situations. We see each of these elements as foundational for social change." (Hoak, Funk, & Berkley, 2021, p 147)

Therefore, three elements might contribute to enhancing sustainability through circus training: entering domains of discomfort, combining different knowledge forms, including embodied learning, and the development of trust.

We are not the first ones to recognize the potential for the circus to become a site of pedagogy. Through a similar path, Wilson (2016) concludes:

"The peculiar meanings and roles acquired by trust in circus practices, where learning entails placing one's integrity and sometimes life in the hands of someone else, and where creation and performing rely on skills of 'bodily listening' and non-verbal communication; and an emphasis on creativity which praises and values the unexpected character of the outcomes of learning or creative processes, and enables to reframe behaviors otherwise classified as marginal, deviant, or pathological, as factors of diversity 'without the minus,' and even as resources for artistry and inventiveness. These features normalize destabilization within social circus spaces, turning them into significant sites of 'politics and pedagogy'" (Wilson 2016, p 6).

Circus performance workshops as "significant sites of politics and pedagogy." Now, that is an exciting thought – and a tentative conclusion.

4. Limitations

Although the findings are inspiring, there are some limitations regarding reaching the same engagement

1. The study aimed to create and explore circus-based methods to build trust. As the format only has been tested with temporary groups of people, no findings are made on long terms implications on established teams.

2. Speaking openly about failure seems to strike different nerves among different targets. A senior target can connect it to experiences at work. These issues might not occur as frequently among a younger generation as there are indications that reflecting on failure is more common.

3. The workshop has shown limitations in terms of time; a workshop of 90-120 min can serve as an initial introduction to the topics. A continuous critique has been the workshop's short length, which ties in with the findings that time is needed to build trust.

5. Conclusions

After having created, through an interdisciplinary, iterative process, and tested a series of circus-based performance workshops in different environments, we can conclude that the experiences point to that trust can be fostered, at least in the short term. Increased trust can potentially enhance social cohesion and sustainability.

Trust is experienced in different dimensions: physical, emotional, interpersonal, self-trust, cognitive- and affect-based. Circus becomes a method, a metaphor, and a mindset, an area of projection and enchantment where we can become otherwise.

Many previous studies have emphasized the psychological skills that can be enhanced: the ability to learn from failures, collaboration, vulnerability, focus, and attention – and we note the same.

Among the crucial factors are the instructors, the physical and emotional space, and the objects used. Of particular importance is the fact that the performance workshops allow for embodied learning.

Finally, the philosophical aspects are at least as important as psychological skills. These kinds of performance workshops can, in the best of worlds, shift how we relate to the world, create new horizons of knowledge, build communities, and cultivate social change.

Abstract

As the world begins to grapple with numerous sustainability challenges such as zero waste, de-materialisation, sustainable consumption, zero emissions and a fair society, product design students must be educated on these key sustainability concepts. In industry, product designers are embedding sustainable values and processes within their everyday design practice when developing new products and services. The Nottingham Trent University (NTU) Sustainability in Enterprise (SiE) project is working to support local businesses within the Greater Nottingham area to help improve their environmental performance across four key areas: People, Products, Processes and Premises. We present a case study whereby for the first time, first-year BSc Product Design students at NTU act as design consultants during a focussed "Sustainability Week" to support local enterprises. During Sustainability Week, teams of BSc Product Design students undertook a project alongside a Nottingham, UK, based chocolate shop and bakery by reviewing their existing product line and packaging solutions. Students selected an existing packaging solution and designed new solutions associated with less and alternative materials for their products. Students learnt through discovery, experience, experimentation, research, practical doing, and other forms of experiential learning. During sustainability week, qualitative data through observation was collected to analyse the development of the sustainability week. Data from students was gathered at the end of sustainability week to gain insight into their learning experience. We collected quantitative and qualitative data to assess the students' experience and the project through a survey questionnaire. A mixed-methods approach was used to analyse the data. The development of Sustainability Week has improved student knowledge on sustainable product development. Delivered sessions promoted knowledge acquisition, skills development, and improved attitudes towards global issues, i.e., Responsible Consumption &

Production (SDG12). Having attended Sustainability Week, a large proportion of the student cohort suggested that this helped improve their understanding of sustainable concepts within product design. Students submitted a physical model and two presentation boards to communicate their proposed new solutions demonstrating through their project outputs and vocational taught sessions improved knowledge on life cycle assessment, methods of communicating sustainable product solutions through design

their basic knowledge of designing for longevity, sustainable design considerations and material selection using material databases. Based on the developed Sustainability Week, the success and positive feedback from students resulted in its integration into the BSc Product Design curriculum, with further improvements planned to enhance Sustainability Week in the future. The implementation of sustainability week in the BSc Product Design curriculum will shape new sustainability-conscious product designers and professionals who have insight into sustainable product development whilst being equipped with dedicated tools/learnings to enhance their professional expertise.

Keywords: University-industry collaboration, Higher education institutions, Eco-design, Undergraduate teaching, Sustainability education, Curricular innovation.

1. Introduction

In recent years the demand for sustainability to be fully integrated as a core concept/topic within product design and design engineering education has continued to grow globally (Ramirez, 2006; Ramirez, 2007; Watkins & Lofthouse, 2010; Seay, 2015; Ashour, 2020). It has been recognised that sustainable product designers require additional knowledge and skills beyond traditional design education, thus highlighting that sustainable product design education should be fully integrated into the core design curriculum to have an impact (Watkins et al., 2021). Sustainable product design is an essential topic that needs to be taught across the product design and design engineering sector; however, it requires specialist knowledge and an in-depth understanding to deliver this successfully/effectively. Future designers and engineers must learn how to address sustainability's triple bottom line, i.e., addressing financial, environmental, and social goals (Oehlberg, 2010). Teaching sustainability alongside enterprise and entrepreneurship also offers a unique opportunity to provide an enhanced educational experience to students across the sector, thus enriching their educational experience.

Education for sustainable development has been addressed in scientific and grey literature in the last years. In a recent study, (Lozano et al., 2017) conducted a literature review to link pedagogical approaches adopted in Higher Education Institutions (HEI) and how they may affect sustainability competencies. For instance, systems thinking is a competence that underpins understanding the interlinkage issues that underpin sustainability problems. According to the framework by Lozano et al (2017), system thinking could be fostered by universal approaches such as case studies, mind and concept maps and project and/or problem-based learning. At the same time, these authors highlight that systems thinking can be nurtured through environmental education, e.g., eco-justice and community and place-based environmental education.

With a topic such as sustainability, it is important that students learn in an environment conducive to exploring their beliefs and values in relation to the topic. This type of learning is best conceived through experiential learning and is best facilitated by a process that allows students to draw out their beliefs and ideas to be examined, tested, and integrated with new, more refined ideas (Passarelli and Kolb, 2012). Teaching sustainability through project-based learning and in the context of experiential learning has also

when considering new product development (Zancul et al., 2017). Embedding sustainability into design/engineering education has been a topic of discussion in recent years (Humphries-Smith, 2007; O'Rafferty, 2008; Watkins & Lofthouse, 2010; Watkins et al., 2021), with academics identifying that more sustainability focussed education should be embedded within the curriculum.

NTU's vision is to create the university of the future, as such one of the six key strategies is to "Embrace Sustainability" (NTU, 2022a). This is also a core research theme which aims to bring academics and industry together to explore/influence low carbon technologies, sustainable consumption, green mobility, and government policy to improve the future of our planet (NTU, 2022b).

Although sustainability is a key strategic theme at NTU, it is important to recognise that within many of NTU's themes, creating links and connecting with industry/enterprise is critical, especially within the education context. 'Therefore, moving forward in today's economic climate, students must engage with industry and enterprise as early as possible in their education in the higher education setting. By engaging with stakeholders and industrial sector experts, enterprise focussed education enables students to experience life beyond the traditional learning setting. At the same time, previous studies have shown the valuable benefits of students' insights into industrial practices (Piekarski et al., 2019). Following the UK QAA 2018 guidance, NTU has identified that all students should have an opportunity to engage with enterprise and entrepreneurship within their subject of choice (Advance HE, 2019).

The 2018 European Entrepreneurial Competence Framework, which also informs the QAA guidance, encourages embedding enterprise within the curriculum. McCallum et al (2018) has also identified that entrepreneurship capability is a core competence for life. It is relevant to personal development and fulfilment whilst also contributing to progression in employment and initiating new ventures ranging from community campaigns and social enterprises to new start-up businesses. Jones (2018) also identifies an increasing demand for entrepreneurship education across all levels of education globally, thus suggesting a need for pedagogy for entrepreneurship across all teaching and learning contexts.

At NTU, the Sustainability in Enterprise (SiE) project partly funded by the European Regional Development Fund (ERDF) aims to combine sustainability and enterprise together. The SiE project supports small and medium-sized enterprises (SMEs) in Greater Nottingham to reduce their carbon emissions. The SiE project blends sustainability and enterprise/entrepreneurship to provide specialist knowledge and skills in sustainable business operations, building management, product design, and employee engagement. The SiE project also provides support in multiple ways, including offering a student sustainability consultancy from two schools at NTU: the School of Architecture, Design, and the Built Environment (ADBE) and Nottingham Business School (NBS). While NBS has a specific module related to the SiE project that students can opt into to support SMEs, ADBE is still in the early stages of integrating sustainability-related skills into its curriculum.

Sustainability-related skills are currently still added in a non-systematic way within ADBE. Thus, the SiE project provided funding from NTU and the ERDF to support ADBE's journey into integrating sustainability education more systematically into the curriculum. This paper shows how sustainability-

undergraduate education). Students supported an SME in reducing its carbon emissions by offering alternative packaging alternatives. It enhanced students' education on sustainability and allowed first- year students to gain experience in a work-related project, offering the opportunity of a site visit and interaction with a business. The project was set up to help businesses fully understand their current carbon emissions and identify effective carbon reduction measures. Subsequently, the project also offers financial support to help businesses act on carbon after enrolling in the scheme and conducting a project (NTU, 2022c).

Within the product design sector, the SiE project also offers a product design consultancy whereby commercial product design consultants offer a wealth of design experience to help reduce the carbon impact associated with products or packaging. Services available include an independent carbon footprint of a company's existing products via a lifecycle analysis, initial research into the design challenges within a business and market context, design consultancy focused on waste reduction and a second lifecycle analysis of a redesigned product to quantify the associated carbon reduction (NTU, 2022c). The product design consultancy resources are also delivered in collaboration with students from ADBE, with concepts taught within specialist sessions.

Collaborating with the SiE project has allowed students to gain their first experience of working with a real-life client in an enterprise setting, whilst also embracing sustainability and sustainable design principles. Throughout this paper, insights are provided on the development of sustainability week, providing understanding, reflection, and student feedback from an end-of-project survey. Finally, recommendations are presented on how to adopt further sustainability-related product design education informed by enterprise for other courses and institutions across the design and built environment sector.

2. Methods

Thirty-seven students split into ten groups of three to five. Each group was set the design challenge of redesigning an existing packaging solution for a female-led chocolate shop and bakery in Nottingham, UK. The outcome needed to be a packaging solution associated with the use of less materials or materials with less environmental impact. The student groups were required to explore the materials used for the existing packaging solutions and the ease of use and assembly of the packaging. It was also crucial that the capabilities of the mass manufacturability of the current and future packaging solutions were reviewed.

A key aspect of the design challenge was adjusting the packaging design and materials whilst maintaining the company's identity. 'Students were required to seamlessly implement the brand values of the female-led chocolate shop and bakery into any designed packaging solution, especially considering the product range focusses on lovingly hand-painted artisan chocolates and deliciously indulgent bakery treats. The brand's personalisation needed to be conveyed through any redesigned

packaging whilst balancing the sustainability aspirations. Critically, the students were required to ensure any product solution adhered to a more sustainable solution, when compared to the original product.

A traditional design sprint methodology approach typically used in industry was adapted which to tackle the business problems allowing the students to complete the design challenge within the sustainability week time scale. In this case, the student cohort were taken through a streamlined design thinking-based

design framework which is often used by design teams to improve the likelihood of producing a successful solution; this is often a product or service (Banfield et., 2015).

Design sprints are used to solve big problems and test new ideas. For this to be successful, a range of elements from the design process are utilised; scientific methods are combined with design activities in combination with philosophical viewpoints and perspectives. Knapp et al (2016) presents a structure/framework whereby a range of focussed activities are utilised to allow successful design sprints to be completed within just five days. Integrating design sprints into the classroom or a design studio is a significant challenge, especially for first-year product design students who have only just started their design education journey and therefore have only begun to embrace the design studio culture and compliance with structured design processes.

Integrating design sprints into classrooms as well as exploring new active learning tools for project- based learning has been successfully utilised in various sectors ranging from human computing, UX/UI design, engineering, and industrial design (Knapp et al., 2015; Ferreria & Canedo, 2020; Ferreria & Canedo, 2019). Many researchers have identified that design sprint activities must be run in a timely manner in order to rapidly focus product innovation to drive more valuable outcomes (Ferreria & Canedo, 2019). The sustainability week design sprint activity schedule is presented in Figure 1.

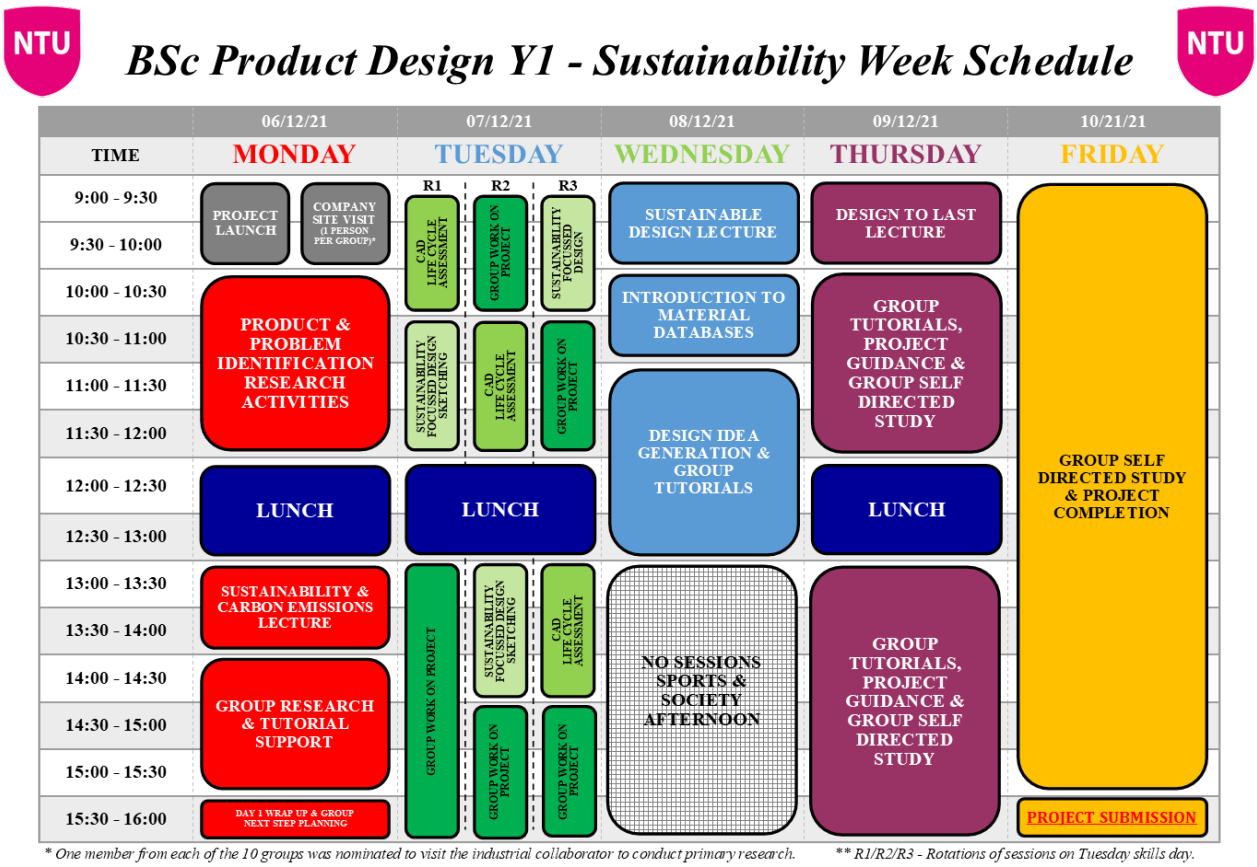

***Figure 1**. Sustainability Week Overview Schedule.*

In the adapted design sprint approach, a variety of lectures, workshops, and short research and design activities were integrated into a structured week whereby the students' groups were able to redesign an

structured set of activities; throughout the week research, design sketching, computer-aided design (CAD), material database exploration, product development and modelling and final design realisation/presentation was completed (Figure 1).

Following the completion of sustainability week, an online survey with open and close-ended questions was created based on previous work on learning and teaching sustainability in higher education (Sandri, 2014). The survey was distributed using Microsoft Forms. It was also designed to collect student demographic data for suitable results analysis. Participation in the survey was entirely voluntary and was sent to the student cohort to ascertain their understanding of the topic and their experience of sustainability week. All quantitative questions utilised within the survey were measured using a 5-point Likert scale. The survey comprising of twenty-one questions aimed to establish the following:

- Student interest on the topic of sustainability prior to the commencement of sustainability week.
- Student prior experience with sustainability/sustainable design principles.
- An understanding of the importance of the topics learnt and activities that were undertaken during sustainability week.
- The students' successes and challenges during sustainability week whilst completing the design challenge.
- Student perception of their thinking on sustainable design after the completion of sustainability week.
- Overall satisfaction with sustainability week and the learning completed.
- Understanding the importance of sustainability in future professional practice and career development.

3. Sustainability Week

Sustainability week aimed to improve student knowledge on sustainable product development whilst promoting knowledge acquisition, skills development, and improved attitudes towards global issues. The topic of sustainable product design/development refers to the design process that considers the source of natural resources as part of the design. Fundamentally sustainable design seeks to reduce negative impacts on the environment. As young aspiring designers, students were asked to consider their role as they move toward living in a sustainable world. Part of their journey throughout sustainability week was to consider their impact on the environment when creating products and services, including reflecting upon environmental, social, and economic impacts whether this is at the initial phase of product development or at product end life. As such, the following session types/activities were conducted throughout the week:

Product Design Studio Sessions

Throughout the week, design studio sessions were integrated to facilitate project development and student group work. Students were briefed at the start of the day with the program of activities which included

methodology, the design studio sessions were broken down into short individual activities whereby the students were empowered to complete specific rapid research activities, utilise tools such as Miro (a visual collaboration platform) to share work, conduct ideation activities based upon previously taught ideation methods from ideation workshops, complete product modelling and experimentation, produce product visualisations for the submission of client-ready presentation boards and finally produce a functional presentation worthy prototype/model.

The design studio sessions also allowed the students to work collectively and as individuals on elements of the project to meet the final deliverables. Throughout the design studio sessions, the supporting academic staff and guest speakers/experts provided group tutorials while also encouraging self-directed group study. The daily ordering of activities (Figure 1) was set out to facilitate the projects progression- Guest speakers introduced key topics throughout the week at timely checkpoints providing key reminders of the sustainability topic which needed to be fully considered. Each design studio session was also linked to the lectures provided, or skills focussed sessions delivered during the week.

Sustainability & Carbon Emissions Lecture

This session aimed to make students reflect on their values, perceptions, and actions (critical thinking and analysis) and understand design decisions' connectivity and cause-effect relationships (system thinking). Students were given an overview of sustainability concepts related to life cycle thinking and the importance of calculating carbon equivalent emissions to quantify the impact. Food production and packaging were used as case studies to highlight how decisions on material use can affect emissions. Case studies are among the pedagogies with a high likelihood of addressing critical thinking, analysis, and systems thinking competencies (Lozano et al., 2017).

Students were also given multiple examples of how design-related decisions often have irreversible effects that can potentially increase social inequalities, environmental degradation, and economic disparities. Students were taught about greenhouse gas (GHG) emissions, their different impacts, and sources. Lastly, a preliminary overview of circular economy principles compared to a linear economy introduced the first discussion into future design approaches, using the waste hierarchy pyramid (DEFRA, 2011) and the 5R's Refuse, Reduce, Reuse, Repurpose, Recycle as the lens.

Sustainability Focussed Design Sketching Session

This session aimed to inform students on how to effectively communicate key sustainable principles regarding their designs in sketch format. This session focussed on communicating packaging products via storyboards. Storyboards are a traditional method of communicating a written story, screenplay, scene, or scenario in many different industries. However, they are a very useful tool in communicating design concepts. Storyboards can be used to stimulate creative thinking, planning projects, collecting ideas, communicating concepts, illustrating key aspects of a design, or presenting the understanding of the big picture (Birchman & Sadowski, 2006).

storyboarding, including movements/actions such as unfolding, assembly/disassembly, deconstruction etc. This session ultimately allowed the students to visually communicate and sketch packaging solutions with each other and potential clients frame by frame, whilst communicating the sustainability story behind their ideas.

Computer Aided Design – Life Cycle Assessment Session

In this session, students were introduced to the basics of conducting a life cycle assessment (LCA) using SolidWorks. SolidWorks is an industry-standard solid modelling computer-aided design and computer-aided engineering application published by Dassault Systèmes. SolidWorks is designed to help designers and engineers conceptualise, create, validate, communicate, manage, and transform innovative ideas into great product designs (SolidWorks, 2022). Within this session, students were taught step by step how to complete a LCA using the software, thus providing them with information on how to make the most environmentally friendly decisions throughout the design process of a product.

The SolidWorks Sustainability plugin/feature integrates LCA directly into the engineering design process, providing insight into a product's social, environmental, and economic conditions, thus allowing designers to be environmentally conscious about their designs. Within this session, students were taught how to model a piece of packaging and its multiple components, apply material settings to the components and then fully assess the sustainability of the packaging solution by completing their first LCA.

Sustainable Design & Material Selection Session

In this session, students were introduced to a wider range of sustainable design principles and topics. Critically, the student cohort were introduced to the social implications of sustainable design, such as social equity and fairness, as well as designing for the needs of people and communities affected by the production, mining, and extraction of raw materials. Students were further reminded about approaches to design using the concepts of the waste hierarchy pyramid (DEFRA, 2011) and the 5R's Refuse, Reduce, Reuse, Repurpose, Recycle, as well as being introduced to key concepts and sustainable design considerations such as The Waste Electric and Electronic Equipment (WEEE) Regulations (Health & Safety Executive, 2022), Restriction of Certain Hazardous Substances (RoHS) Directive (European Commission, 2011), design for sustainable behaviour (Selvefors et al., 2014), design for disassembly and design for modularity.

Furthermore, the student cohort were introduced to Ansys Granta EduPack (Ansys, n.d.) a piece of software that provides and enhances undergraduate materials education and includes a database of materials and process information, materials selection tools and a range of supporting resources. This software helps teach appropriate material selection based on the work completed by Ashby and Cebon (1993) which focusses on material selection in mechanical design. Material selection in relation to product design is fundamental (Ashby & Johnson, 2013), and ultimately directly impacts the perceived sustainability of a product from a material selection standpoint, design for modularity, design for disposal and energy consumption standpoint. An introduction to material selection was presented, including the

principles. Within the software, students were able to access the sustainability package and explore how to generate charts that compare materials and the properties of the different materials to justify their selection and implementation into products. Additionally, students received demonstrations and step-by-step guides on how to critically evaluate a product's environmental impact through the eco audit tool.

Designed To Last Lecture

The session focussed on "Designed To Last" was centred around recent research on product longevity and how to increase this as a part of the circular economy discussion. Product longevity function is an important element of environmental sustainability by slowing the rate of consumption. When discussing product longevity in the design context, physical durability is an important deciding factor for the actual product life. Also, the user's attachment, the ability to repair and maintain a product and the business supporting the product will all influence the longevity of the product.

Working with product longevity and being presented with these opportunities can hopefully enable students to be more cautious in their design process. The students were firstly presented with 14 barriers that designers, companies, and users need to overcome to produce products with high longevity (Jensen et al. 2021a). These barriers form insights into obstacles for the students that might not have been considered previously. Based on a discussion of these barriers and their relevance to the student's current projects, they were then presented with real-life cases from 18 producing companies and their solution principles to the barriers (Jensen et al. 2021b). As the cases differed significantly in both marked solutions and aim, the students could select and adopt the most appropriate solution principle for their own project. Based on the presented barriers and solution principles, the students worked to incorporate considerations regarding the product longevity, ranging from limiting the number of parts needed or increasing the modularity of the product to creating a more personal experience between product and user to improve the user's experienced attachment towards the product.

4. Results and Discussion

Thirty-seven students took part in sustainability week, of which twenty-two students voluntarily completed the anonymous end-of-week survey representing a 59% response rate. The male to female response rate was 91% male to 9% female; however, it is worth noting that the student demographic for the 2021/22 academic year for BSc Product Design first year cohort is predominantly male, representing 84% of the student cohort. The average age of respondents was 20.3 years old, with the student cohort age range consisting of students aged 18 – 30.

Results show that the higher the student age, the more interested they are in learning about sustainability/sustainable design. Students more interested in learning about sustainability/sustainable design typically haven't studied or had previous experience with sustainability/sustainable design before sustainability week. The overall satisfaction with sustainability week was positive; 15 out of 22 students who completed the feedback survey were satisfied or extremely satisfied with sustainability week in understanding sustainable development principles. 19 out of 22 students agreed or strongly agreed that

product design.

Student feedback also showed that the different sessions were important or extremely important (Figure 2). While discussing ideas with lecturers and guest speakers was the session considered most important, students felt the design sketching session was only moderately or somewhat important. The perception of the design sketching session may have been deemed less important by the students as they receive weekly design sketching classes throughout the entire first-year curriculum. Conversely, this might also be explained by the fact that product design students often prefer to "learn by doing" (Lawson, 2006, p.7). Therefore, in this situation, had the design sketching classes allowed the students to focus on the communication of their specific designs through the storyboarding sustainability focussed activity, rather than just teaching the fundamental skills, this session may have been better received by the students. It is also recognised that product design students prefer to "learn by doing" and through experiential learning experiences, whether this is by experiencing handling materials (Parisi et al., 2017) or through hands-on project-based learning in a design studio setting (Gomes et al., 2018).

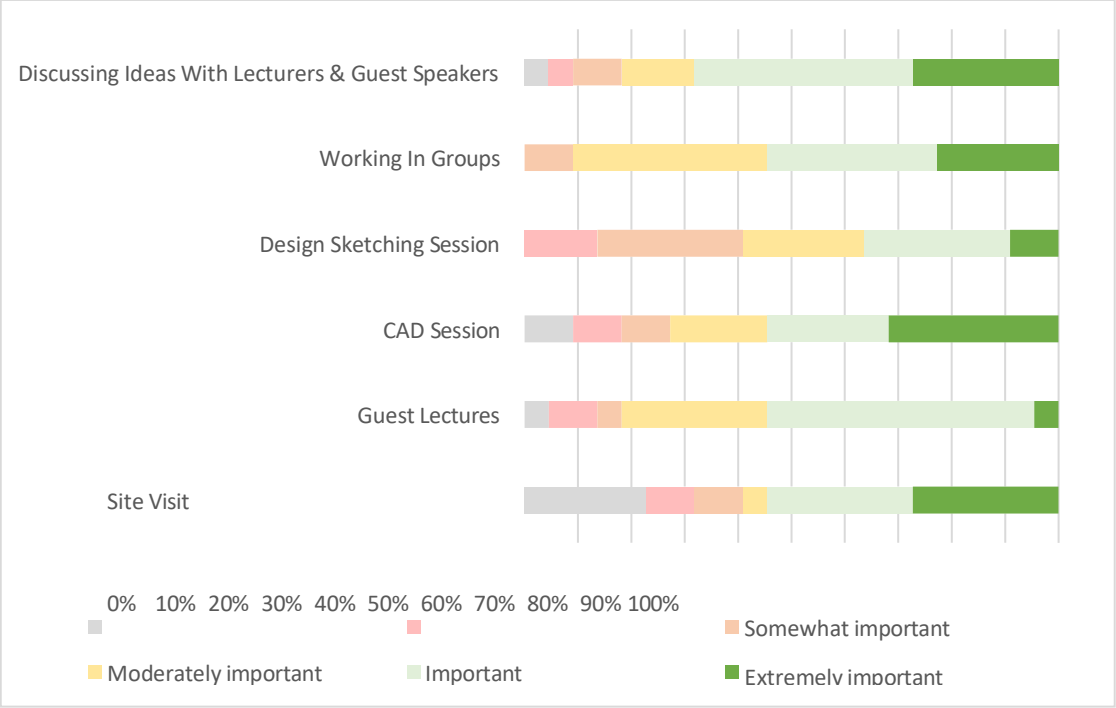

***Figure 2**. Level of important of the different Sustainability Week sessions.*

Sustainability week was the first experience for most students to integrate sustainability-related concepts into the design phase of a project. At the end of the experience, 11 out of 22 students stated they were very or extremely confident in applying sustainability principles/ideas/theory in their professional careers. From the survey results, additional key findings concerning the student experience and future sustainable practices were as follows:

- 15 out of 22 students identified it was either very relevant or extremely relevant for them to work on a project brief based on a product from a company/enterprise.
- 19 out of 22 students identified that sustainability week was very relevant or extremely relevant

- 18 out of 22 students agreed or strongly agreed that they believe sustainability is relevant to them personally.
- 19 out of 22 students agreed or strongly agreed that sustainability week should continue to be part of the product design degree program.
- 18 out of 22 students agreed or strongly agreed with the statement that "they would engage in more initiatives like sustainability week in the future".

Students reflected upon the activities conducted throughout sustainability week, identifying the sessions they felt helped them learn the most about sustainability and the related principles and ideas; key quotes from the survey results included:

"Session with [Guest Speaker 2] about product lifecycle, as this made me more aware that the products we design could have a secondary use to prolong the life of the product". (P1)

"Thinking about the whole supply chain as a whole rather than just the finished product and that some sustainable materials are in fact not as sustainable as they claim to be". (P3)

"The presentations from the guest lecturers were insightful, and the sustainability week project was beneficial as it improved knowledge on sustainable materials through research". (P4)

"The CAD session was very interesting; learnt about the sustainability features in SolidWorks as well as interesting information presented…" (P6)

"The CES [materials database] session because it's such an important and useful piece of equipment. Also, the storyboards because they are also applicable to other projects we do. The talks given by guests were interesting to give an insight into what they do". (P12)

"The CAD session gave a practical way to learn about sustainability and how to achieve it in modelling". (P14)

Students were asked if they found any of the sustainability concepts or theories challenging to understand during sustainability week. A variety of topics were taught in a short space of time during the sprint-inspired project, thus reinforcing some topics that may be needed in future projects. Responses to this question provided little insight as most students found aspects of the design task challenging and not necessarily the sustainability concepts/tools taught:

"Trying to come up with a design that used a single material and not using any glue or other fixings, developing the net became the biggest challenge, and researching existing products that do similar things and taking them apart really cleared up the methods they use". (P3)

"The most challenging theory was trying to make a universal packaging [product] that could be increased and decreased in size whilst also saving packaging". (P12)

Students were also asked if there were any 'light bulb moments' that helped them learn about sustainability during the week. Interestingly a variety of topics were raised based on the guest lectures delivered and the self-directed research conducted in groups:

"Yes, when further research was done into what is sustainable, because it was confusing at first, once the processes of how long something takes to decay was researched, and what conditions it needed, it was easier to find materials that met the needs of the company as well as being sustainable". (P5)

"During the [guest] lectures and a presentation where some examples have been shown and how the product can be used for different things". (P7)

"Price of material production changed our outlook on what our design was made of". (P17)

Over the course of sustainability week, students identified that finding the balance between design creativity and realism in combination with suitable sustainable design considerations was a big challenge. The survey asked students to reflect on any aspect of the project brief they found challenging:

"The biggest challenge was finding the balance between design and sustainability, as the client relies heavily on presentation. We found an abundance of choice when it came to choosing sustainable materials though". (P4)

"Finding a material that's suited what the company wanted as well as being sustainable". (P5)

"Producing a packaging product that is creative and different but also viable as a real-world option". (P10)

"Trying to make our design more sustainable than the original. It took a while for us to make something worth producing, by making it reusable". (P15)

The integration of sustainability week into the BSc (Hons) Product Design first-year curriculum has been successful and has addressed some challenges that Watkins et al (2021) identified. Although it was not possible to overcome all of the challenges Watkins et al (2021) identified, the integration of sustainability week has addressed factors such as integrating sustainable product design into the core curriculum as a standard and not as an elective subject. Sustainability week has also ensured the topic was covered thoroughly and not in the discipline's broad, holistic nature. This is often the challenge in a culture of reducing contact hours and growing pressure from other aspects of the curriculum. Sustainability week also allowed focused teaching on specific aspects of the discipline by experts rather than taking a holistic approach by providing a general appreciation for sustainable product design within the broader discipline of design. Sustainability week also allowed students to obtain, comprehend and apply resources to project work which supported industrial partners/collaborators on a focused sustainable product design project/challenge.

Furthermore, the success of sustainability week and the SiE project has now led to the further development of more rapid sprint informed design projects within the Product Design Department at NTU with further

of the 2022/23 academic year. The drive to embrace sustainability and a net zero carbon strategy is an ethos NTU has embraced at an institutional level and continues to develop. It is an important driver behind how students think and their decision-making. This is demonstrated in the survey results feedback. A selection quotes from the survey demonstrate how students perceived sustainability concerning the sectors professional practice and their own professional practice:

"It will most likely play a key part in any design sector that I'll choose to go into and will influence the outcome of many future projects to come in terms of materials, manufacturing, and societal impact." (P6)

"Minimising throwaway items such as packaging, labels, stickers and trying to use reusable methods of packaging or schemes to reduce throwaway and offer bring back pay back schemes." (P18)

"In a design setting, I expect that sustainability reports will have to be produced for every product you design." (P19)

"Designing in a smarter manner to extend a product lifespan. Also, the removal of planned obsolescence." (P21)

Moving forward other methods of integrating and assessing education for sustainable development within the curriculum are to be explored. It is strongly recommended that institutions globally do so too. In addition, based on the survey results collected, these demonstrate that there is a demand from students to learn more about sustainable product design and sustainability in enterprise. The students identified that they learnt many new skills throughout sustainability week as demonstrated by the survey feedback:

[Improved skills include:] "Material science, working with a client, being more conscious of sustainability." (P1)

[Improved skills include:] "How to use material databases, how to explore multifunctionality, how to use CAD [Computer Aided Design] to better understand the impact of production." (P13)

[Improved skills include:] "How to look at sustainable materials i.e., effect and function." (P18)

[Improved skills include:] "How to be more sustainable in CAD [Computer Aided Design], how to work faster as a team and effectively manage time." (P22)

This recommendation does present its challenges; Watkins et al., (2021) also identifies many of the same challenges faced throughout the sustainability week project. There is a growing demand from industry for graduates to have not only an appreciation of the topic, but to have a detailed understanding and awareness of sustainability in addition to possessing sustainability focussed skills. Academics and academic institutions globally would benefit from continually investing in sustainability driven education. To enhance sustainability projects moving forward, it is necessary to invest further in developing or redeveloping classes whilst also further supporting research into sustainable product design/development to ensure the latest knowledge generated is disseminated at the undergraduate level.

There is also a need to promote the demand for sustainability skills in graduates in industry and ensure students are aware of this demand. Professional institutions and course accreditors are also demanding this as part of their code of practice. If sustainability is taught in the correct setting, and supported by sustainability focussed projects, students have proven they are prepared to embrace this much quicker

and subsequently they recognise the importance of this much quicker. The drive by ADBE and the SiE project team has also helped promote and involve academic staff and students in sustainability initiatives and strategic sustainability plans. Sustainability week is a clear example of this, and similar initiatives should be promoted institutionally and sector wide; this is another recommendation highlighted by Watkins (2010) in earlier work conducted on the integration of sustainable product design knowledge and practices in HE.

Despite the challenges identified, integrating the design sprint into the first year is a valuable first step in students' education for sustainability. It represents the first overview of concepts that will be used and experienced in more detail throughout the course. Previous research has discussed the benefits of integrating first-year sustainability-focused content (see, e.g. Coops et al., 2015). Particularly, to create a sense of community between students and staff and expose students to an interdisciplinary teaching team from the beginning of their course.

From the feedback collected, it is evident that students have found the experience of engaging with sustainability week challenging and rewarding whilst also enriching their educational experience. The mixture of activities and session types embedded through a sprint approach has allowed a variety of key concepts and skills to be taught in a short space of time. Although the key concepts have been taught and communicated to a good standard, it is evident that some of the more complex skills, such as LCA, material selection need further integrating into future projects throughout the academic year to reinforce and reapply the taught skills, whilst also interrogating the topic to a deeper level. Students appear to have embraced sustainable design principles within the packaging sector, therefore, it will be interesting to see in future projects whether they can apply the skills and teaching knowledge to a different product sector.

The present study did not assess specifically whether the approach undertaken were effective in behavioural change, but this will be addressed in the following academic year when the same cohort of students, now in year two, will go through another sprint sustainability project. Nevertheless, even though only a minority of students stated being interested or extremely interested in learning about sustainability/sustainable design, the majority confirmed their thinking had changed due to the sustainability week. This cohort of students will go through the next stages of a more in-depth understanding of sustainability concepts and their application to product design, including circular economy principles such as designing to regenerate in year two which forms the next stages of developments of embedding enterprise focussed sustainable design principles into the curriculum.

Embracing Sustainable Principles – Student Outcomes

Throughout the week, students were encouraged to embrace a number of different sustainable design

product. Many students considered how to make the current packaging solution more sustainable, especially when considering the existing materials and manufacturing methods, whilst exploring other options. Students also explored other options regarding materials which could open up new packaging solutions and how the product net could be manufactured and subsequently tessellated to minimise waste during production.

While exploring materials and manufacturing, the students also had to consider the elegance of the brand and the product range, as the texture of the material significantly impacts the perception of the product's elegance to both the client and the customer. Furthermore, suitability and adherence to sustainability values and principles were consistently considered by examining the packaging life cycle and sustainable packaging considerations. The key design considerations the students reflected upon and implemented into their designed product focussed on the following questions posed:

- Is the solution beneficial, safe & healthy for individuals and communities throughout its lifecycle?
- Does the product solution meet the desired market criteria when factoring in the performance vs cost considerations?
- Are materials sourced, manufactured, transported, and recycled effectively when considering renewable energy sources?
- Are product solutions optimised when considering the use of renewable or recycled source materials?
- Can the designed solution be manufactured using clean production technologies and best practices?
- Can the designed product be recovered and utilised in biological and/or industrial closed-loop cycles?
- Does the product solution minimise the mixture of different materials?
- Could compostable and biodegradable alternatives be utilised?
- Has the designed product minimised over-packaging, which can reduce the impact on the supply chain?
- Are there any secondary uses or reuses for the designed solution?

The posed questions consider many of the total life cycle considerations when designing products where both closed loop and open loop life cycle systems are considered (Jawahir et al., 2006). In addition, students are often influenced by the design thinking approaches linked to the circular economy and design guides developed by IDEO and the Ellen MacArthur Foundation (The Circular Design Guide, 2018). Furthermore, the questions posed were also influenced by the 5R's Refuse, Reduce, Reuse, Repurpose, Recycle and DEFRA’s (2011) waste hierarchy pyramid. Based on these taught principles, the student groups were challenged to approach their packaging redesign with these in mind.

Each student group picked an existing packaging solution and thoroughly examined every aspect. Figure

presents a student-designed output demonstrating how an existing product has been redesigned to be manufactured out of a single type of material whilst still being easily manufactured and assembled yet conversely also reducing the number of components needed and variety of materials used.

A key aspect moving forward that needs to be further integrated into any further sustainability week, is the

calculators and templates exist online and within software packages taught within higher education. Introducing this concept earlier within the product design / sustainable education curriculum would allow students to make more valuable and quantifiable comparisons of their design decisions, providing further value to the project partners.

When considering the topic of "designed to last" (Jensen et al. 2021a; Jensen et al. 2021b), to further improve the integration of this consideration regarding product longevity into the student projects, a second "sustainability week" is recommended within the curriculum; as previously discussed, the same cohort of students will experience this in the second year of their studies. In sessions delivered, students should be provided with the opportunity to integrate product longevity considerations in an earlier phase of their project, such as the idea generation process. Further insight on the topic could lead to further co-development of products alongside product longevity considerations, which could help create a more integrated result and improve the total sustainable footprint of products. Furthermore, sessions on the considerations between different sustainable choices in the design process would help improve the students understanding of environmental sustainability and help make them consciously select their solutions.

5. Conclusions

In conclusion, sustainability week has provided an initial platform for enterprise-driven sustainability focused projects to be embedded into the ADBE curriculum at NTU. Using the design sprint methodology allowed the students to focus on sustainability for a week whilst being guided through specific activities and taught sessions. It has allowed the students to become self-supportive and present sustainable solutions to real-life clients. This project has further unlocked the potential for adopting sustainability and enterprise focussed teaching across different settings and has demonstrated how an institutionally driven ethos/approach can benefit academics, students, and industry partners alike to work collaboratively regardless of the setting.

The development and integration of sustainability week is just the start of the wider adoption and focus on sustainable development teaching. As a direct result of the success of sustainability week, further sustainability weeks are planned with consideration on how this model could be adopted across a wider range of year groups and courses across the product design department and also the school. Developing on from the success of sustainability week, the student group were then able to work on numerous projects for the rest of the academic year with a great deal of success. Design competition projects later in the academic year focussed on upcycling and developing products based around the process of sustainable aluminium extrusion design, this allowed further sustainable design principles to be taught and embedded into the student’s design practice. This has now allowed academics to develop longer sustainability focussed projects for the same year group to experience in their second year within the 2022/23 academic year; this would have not been possible had the student group not had this initial intense introduction on the topic.

wider integration of circular economy principles being integrated into the student's daily design habits and model making experience. Schemes are currently in development whereby the actual product making experience in the university's workshops are influenced by these principles from the ground up, whether this be designing and model making at year one or whether this be final year degree show exhibition development.

Finally, one of the most exciting aspects for future development is the possible 'vertical integration' of sustainability weeks, months, or projects across the different levels of degree programs which will lead up to degree shows to showcase the most sustainably conscious products and designers. Sector wide design competitions are demanding students to be sustainably conscious and the success of failure of projects can be defined by the correct application and adoption of these principles. By developing a deeper understanding of sustainable design principles, circular economy understanding etc., this will allow students to also gain a deeper understanding of sustainable or circular design business models which is needed to allow students to know how to make a business case for sustainable products.

Cross course collaboration could help further influence and leverage staff knowledge bases ensuring students hear from experts across numerous subject fields. An initial trial of cross course collaboration is planned with the Engineers Without Borders (EWB) project for 2nd year product design and civil engineering students. The EWB project provides the opportunity for students to build up on their acquired knowledge from sustainability week and apply this to a design challenge that will broaden their awareness of the social, environmental, and economic implications of engineering and design solutions. By sharing the resources required to deliver this complex subject fully and comprehensively this will not only benefit the student cohort, but this will also enable all product design educators to upgrade their knowledge and skills to be able to teach and assess this subject by increasing literacy and expertise in this area both from a design, business, and entrepreneurship perspective.

Funding

This project was run alongside the NTU Sustainability in Enterprise (SiE) project that is part-funded by the European Regional Development Fund (ERDF).

Acknowledgements

The authors would like to thank the BSc Product Design first year student cohort who took part in sustainability week and contributed to outputs presented in this paper.

Abstract

Educators play a critical role while implementing Education for Sustainable Development. Therefore, there is a need for innovative and more powerful tools to prepare educators in making the change to sustainability happen in their schools. This paper introduces the simulation 'Leading change to sustainability in schools', a product of a research & development (R&D) project, which sought to create an online-based simulation to prepare Vietnamese educators for the challenge of implementing more sustainable practices into K-12 schools. This paper aims to present the initial evaluation of simulation in changing knowledge, attitudes related to managing the change for sustainability. The authors conducted a quasi-experiment during four- week teaching session with 32 graduate students in Faculty of Education. As a result, the participants show the significant differences on before and after learning with simulation for their knowledge about sustainability and change management to sustainability, as well as their attitude towards sustainability.

Keywords: education for sustainable development, simulation-based learning, Vietnam

1. Introduction

Transformation to sustainable development requires complex, systemic changes to take place from the individual to the social system levels. Undeniably, traditional teaching methods will lead to missing many connections and interactions which can be explored to solve sustainability-related problems. This would suggest a requirement for innovative and more powerful tools to prepare educators in making the change to sustainability happen in their schools.

In recent years, simulation and serious games focusing on teaching sustainability have been proliferating because of their superior ability to capture the complexity of sustainability problems. In concert with

advancements in simulation technology, this study represents project the 'Leading Change for Sustainability in Schools' simulation for the Vietnamese version. Based on the existing Leading Change for Sustainability (business) simulation, the authors use Research and Development (R&D) to redesign sustainability-oriented online simulations for use in Vietnam's education sector. School leaders and teachers play vital roles in cultivating sustainability awareness and competencies among students, as well as preparing them with the decision-making values and skills needed to foster a sustainable society. Therefore, the 'Leading Change for Sustainability in Schools' (LCS in schools) simulation can be used with prospective and practicing educators to learn how to better lead the change towards sustainability in the Vietnamese K-12 education system.

2. Background

Several conceptual models of organizational change management and sustainability are embedded in the simulation. Change management theories include Concerns-based adoption (Hall & Hord, 2006), change adoption and diffusion (Crandall, Eiseman, & Louis, 1986; Rogers, Medina, Rivera, & Wiley, 2005), systems thinking and strategic change leadership (Senge, 1990; Senge, Hamilton, & Kania, 2015), and change model (Kotter, 1995; Kotter & Cohen, 2012). This model of leading change informed the decision rules and conceptualization of 'change strategies' that are built into the simulation.

The concept of simulation-based learning is derived from constructivist learning theories (Bruner, 1996), and experiential learning theories (Dewey, 1986; Kolb, 1984; Rogers, 1969). This method focuses on learner-centered approach, and active learning which help learners generate required knowledge and skills applicable to reality while those may take after several years' real time period (Salas, Wildman, & Piccolo, 2009; Sauvé, Renaud, Kaufman, & Marquis, 2007).

For sustainability, there are some concepts embedded from triple bottom line (Elkington, 2013), Education for sustainable development (UNESCO, 2002, 2020), whole school approach to sustainability (Tilbury & Wortman, 2005). Especially, the authors refer to Green school project in Vietnam. Because Green school project leans on environmental issues limited perspectives and asynchronously implemented from different regions in Vietnam, the authors also utilize the Sufficiency Economy Philosophy (SEP) model of sustainability which is bestowed by His Majesty King Bhumibol Adulyadej of Thailand over many decades. SEP has been widely adopted as a "people-centred approach to sustainable development" (Wedchayanon & Chorkaew, 2014; Wibulswasdi, Piboolsravut, & Pootrakool, 2011). The SEP was implicated in education and in Thailand there are the model of sustainable school, called Sufficiency-based school project, that make this research a vivid lesson for localizing ESD concept (Dharmapiya & Saratun, 2015). It makes the

authors learnt social and economic conceptions and inherited national and cultural adaptation during redesigning simulation for Vietnamese context.

To evaluate the effectiveness of learning with simulation, this study implements a learning assessment of the knowledge, attitude, and behaviour in sustainability education (Chappin, Bijvoet, & Oei, 2017; Salas- Zapata, Ríos-Osorio, & Cardona-Arias, 2018). The "LCS in schools' simulation sought an ESD-oriented pedagogy that requires all learning domain criteria. Increasing knowledge and attitudes towards sustainability through simulation-based learning can provoke the intent of sustainability behaviour and lead to future behavioural changes. Based on that framework for the learning assessment, in this paper, the authors present the evaluation of learners' knowledge of sustainability and change management and attitudes toward sustainability while learning with 'LCS in schools' simulation. Sustainable behavior reflects how learners understand and think about sustainability reveal through strategic skills achieved during the simulation learning. As the limit of the conference paper, this part will be introduced in further research.

3. Overview of simulation

'Leading Change to Sustainability for schools' (Vietnam) is a web-based simulation that addresses these management and leadership competencies in the context of a school district that is trying to apply 'whole school approach to sustainability' to some pilot schools. It was originated by simulation 'Leading change to sustainability' which is for business context. After revising and redesigning the simulation through R&D cycle, the simulation new version is for Vietnamese context and take places in education scenario (Nguyen & Hallinger, 2022).

Through the internet access, learners can play the simulation anytime from anywhere. The learning objectives for use of the simulation include the following: 1. To gain a deeper awareness of the range of sustainability challenges faced by schools and society; 2. To analyse, plan, and execute a change strategy for helping a school district transform for sustainability; 3. To understand key concepts related to triple bottom line, Education for sustainable development, and sustainable school; and assess their implications for management practice into school context.

The simulation scenario is that the Vietnam Ministry of Education has selected one of the pilot districts for implementing a new project focused on the implementation of sustainability in the education system. This project, so-called 'One Future Project', aims to educate future generation a capable of living in a sustainable society and a sustainable planet. The participants play a role as a member of the project team. During this 3-year assignment, they have responsible to transform educational organizations become models'

sustainable values and practices. This transformation should become evident in daily practices as well as in schools' contributions to the economic, environmental and social development of the society. They are able to lead the pilot implementation of One Future in our district education unit: The District Office, Primary School, Secondary School.

While playing the simulation, players interact with 24 stakeholders in various positions (e.g. head of education department, members of people committee, school principals, teachers, parent representative, trade union officers, etc.). the first goal for players is to reposition those stakeholders as possible from outside Gameboard (i.e., know nothing about sustainability) to the final stage (i.e. fully acknowledge and use sustainable practices in daily life and working) at the end of three years. In order to accomplish this 'change', players spend an annual budget on typical 18 activities that can be used to 'move people' through the five change stages towards sustainability (see Figure 1).

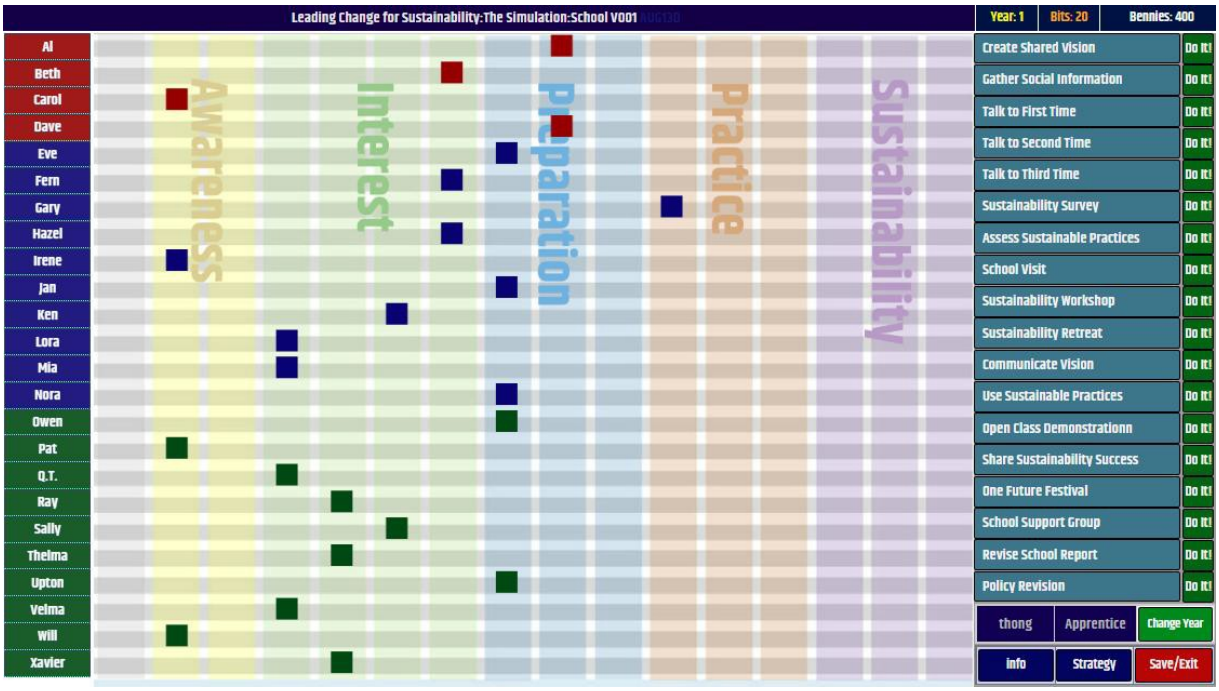

Figure 1. Leading Change for Sustainability in School simulation screen/gameboard (in English)

The second goal for players in this simulation is Bennies (sustainability benefits). Bennies are symbolized for positive impact on the triple bottom-line of the educational organizations as it leads changes towards achieving a balanced set of economic, environmental, and social outcomes. The conception of Bennies is aligned to the triple-bottom-line of social, environmental, and economic benefits (Elkington, 1994, 2013). Consequently, if learners can motivate the simulation's stakeholders to embrace sustainable practices that result in progress toward new social, environmental, and economic goals, they could win a lot of Bennies.

Players interact in this simulation within a three-year simulated timeframe. When starting each year, players receive a new budget to implement activities designed to move the project forward (see activities on the right side of Figure 1). Each of these acts has a cost as well as an underlying purpose.

sustainability, education for sustainable development, sustainable school and the purpose of the project (e.g., Sustainability Survey, Assess Sustainability Practices, Talk with People). Other activities are used to motivate and inspire stakeholders to engage with the change in schools (e.g., Create Shared Vision, Communicate Vision, and School Visit). Some activities are used to prepare stakeholders for the implementation of new whole school approach to sustainability (e.g., Sustainability Workshop, Sustainability Training, Open Class Demonstration). Other practices focus on supporting the practical use of sustainable practice (e.g., Use Sustainable Practices, Share Sustainability Success, and School Support Group). Finally, various activities are utilized to incorporate sustainability into the educational policy structure and school culture (e.g., Revise School Report, Policy Revision, School Festival).

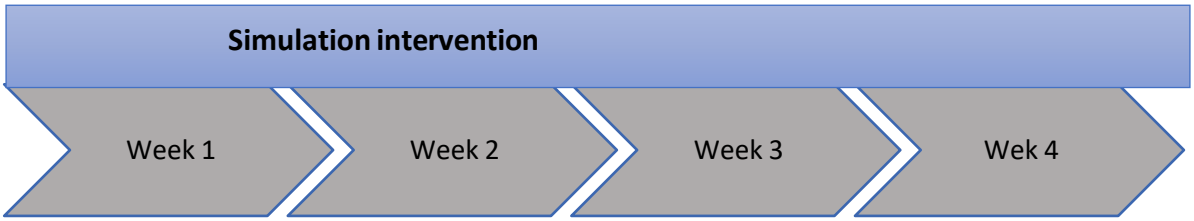
Both during and at the end of each play, participants can observe the rate and patterns of changes in the stakeholder's positions on the playing field as well as the accumulation of Bennies. As the players conduct the activity, a change takes place (i.e. stakeholders will move or not). As Bennies increases, players can observe the effects of new practices on the triple bottom line. Their results are reflected and evaluated in six levels of management from apprentice to master change. The evaluation is measured by two main objectives: 1) how many stakeholders have reached the sustainability stage; and 2) how many Bennies have earned (i.e. impacted Triple Bottom-Line). When players reach the higher levels (e.g. Expert and Change Master), it reflects the use of a 'Stronger Change Strategy' based on the change theories embedded in the simulation.

4. Methods

Research design

This research adopts a quasi-experimental design without a control group. This single-group pretest-posttest design plays an important role in education as it can prove an intervention promise during the development phase (Marsden & Torgerson, 2012). Pre-test and post-test design without a control group faces threats of validity (Campbell & Stanley, 1963; Shadish, Cook, & Campbell, 2002). However, much research in the education field did not include a control group because implementing stages usually carry on a semester or a specific number of teaching lessons, and depend on the simulation complexity (Gatti, Ulrich, & Seele, 2019).

Though the project uses mixed method design with both formative and summative measurements to evaluate the simulation effectiveness, this paper presents summative evaluations which combine pre-post- test on learners' knowledge, attitude for change to sustainability.



- pretest 1: knowledge about sustainability and change management to sustainability, and attitude on sustainability
- posttest 1: knowledge about sustainability and change management to sustainability, and attitude on sustainability

Figure 2. Summative Evaluation Scheme during 4 weeks

Sample size

This study uses the convenience sampling method. Because it is difficult to create a randomized sample and control group with the teaching and learning process. The quasi-experiment is held during four-week teaching sections with 32 participants. Those people are graduate students at Faculty of Education, University of Social Sciences and Humanities, Vietnam National University, Hochiminh city. Though, their work varied from teachers, school leaders, educators, staff in schools and university in Vietnam. Participants consist of 11 male and 21 female graduate students.

Instruments

Inspired and adopted others scholars' learning assessments (Chappin et al., 2017; Salas-Zapata et al., 2018), the authors designed a pre-test & post-test for the learning assessment regardless of two domains knowledge and attitude. The pre-test questionnaire was distributed in week one before class started, and the post-test questionnaire was distributed in week four when students took the simulation examination. These identical pre-test and post-test comprise the sustainability knowledge test, and sustainability attitude (mindset). The sustainability attitude test consists of 15 questions using a 5- point Likert scale (from total disagree to total agree). Plus, the participants self-evaluate their knowledge on sustainability issues, including sustainable development goals, circular economy, education for sustainable development, environmental education, global citizenship, social sustainability, triple bottom-line, social responsibility, sustainable school. The participants choose one from four statements which is self-rated their knowledge. i.e. 1= "I don't know about it", 2 = "I've heard of it but don't know much about it", 3 = "I could explain this but only in general terms", and 4 = "I could explain it well". The knowledge about change management to sustainability focuses on how participants involve change to sustainability in schools in particular situation. It is the 12 multiple-choice questions.

Data analyses

The data from participants were collected and recoded for identification protection. After that, the

evaluated the participants' knowledge on sustainability and change management, as well as attitude on sustainability. The difference of mean score before and after learning with simulation. As small sample size (N = 32), the normality test was conducted by Shapiro-Wilk test. Plus, the Cronbach Alpha score is also reported to check the validity of knowledge on sustainability test, and attitude on sustainability test.

5. Results and Discussion

Demographic information

Among 32 participants, there are 11 male and 21 female graduate students. They are from various education working places such as teachers, vice-principals, staff in universities and schools, NGO officers, etc. Theirs working experiences in education sectors were varied. There were 14 participants (43.75%) who has from 1 to less than 5 years of experience; 11 participants (34.37%) from 5 to less than 10 years of experiences, and 7 participants (21.87%) had more than 10 years of experience in education sectors. For digital capacity, participants rated them self through four statements from limited to proficient. As a result, 22 of participants have moderate digital capacity (68.8%). Seven participants have advanced digital capacity (21.9%); and only three people have struggles with modern teaching and learning approach (9.4%). The authors also checked their experience of learning and teaching with simulation to estimate the difficulty which participants might have. There were only nine participants who have experiences with learning or teaching with simulation (28.1%). In short, the participants have little experiences on learning with simulation.

Knowledge on sustainability

Knowledge on sustainability were compared before and after learning with simulation "LCS in schools". The range for scale was from 1 to 4. On average, participants understand more knowledge (M = 3.16, SD = 0.46) than before taking the learning session with simulation (M = 2.33, SD = 0.54). This improvement, 0.83, 95%CI [0.61, 1.06], was statistically, t (31) = 7.49, p<.001.

Knowledge on change management for sustainability

Knowledge on change management for sustainability were compared before and after learning with simulation "LCS in schools". Maximum score for change management knowledge test was 12. On average, participants gained more knowledge (M = 8.13, SD = 1.6) than before taking the learning with simulation (M = 6.22, SD = 2.72). This improvement, 1.91, 95%CI [0.89, 2.93], was statistically, t (31) = 3.81, p<.001.

Attitude towards sustainability

Attitude towards sustainability were compared before and after learning with simulation "LCS in schools". The range for attitude scale was from 1 to 5. On average, participants increased their attitude to sustainability (M = 4.05, SD= 0.37) than before taking the learning with simulation (M = 3.74, SD = 0.46). This improvement, 0.31, 95%CI [0.16, 0.47], was statistically, t (31) = 4.03, p<.001.

Table 1. *Paired sample Test.*

Paired Samples Test

		Paired Differences					t	df	Sig. (2-tailed)
		Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
					Lower	Upper			
Pair 1	sus knowledge_post - sus knowledge_pre	.83	.63	.11	.61	1.06	7.49	31	.000
Pair 2	change knowledge_post - change knowledge_pre	1.91	2.83	.50	.89	2.93	3.81	31	.001
Pair 3	sus attitude_post - sus attitude_pre	.31	.44	.08	.16	.47	4.03	31	.000

Table 2. *Descriptives.*

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	sus knowledge_post	3.16	32	.46	.08
	sus knowledge_pre	2.33	32	.54	.10
Pair 2	change knowledge_post	8.13	32	1.60	.28
	change knowledge_pre	6.22	32	2.72	.48
Pair 3	sus attitude_post	4.05	32	.37	.07
	sus attitude_pre	3.74	32	.46	.08

Assumption

As the small sample size (N=32), the authors conducted normality distribution test with Shapiro-Wilk test. Only the p-value of the Shapiro-Wilk of the knowledge on sustainability test was .508 > .05, reflecting that this knowledge on sustainability test was normally distributed. It is assumed that After minus Before learning with simulation did not follow the normal distribution for knowledge on change management (p- value is .007), and attitude to sustainability (p<.001). So, those testes were considered robust for moderate violation of the normality assumption. Thus, in further research the authors would use larger sample size or replace with Paired Wilcoxon Sign Rank Test for knowledge on change management and attitude to sustainability.

Table 3. *Normality Test.*

		W	p
sus knowledge_post	- sus knowledge_pre	.970	.508
change knowledge_post	- change knowledge_pre	.902	.007
sus attitude_post	- sus attitude_pre	.8333	< .001

Note. Significant results suggest a deviation from normality.

For the reliability test, the knowledge on sustainability and attitude to sustainability construct were estimated the internal consistency with Cronbach's alpha value. The results showed Cronbach's Alpha for knowledge on sustainability consisted of 9 items (α pre-test = .884, α post-test =.828), attitude to sustainability consisted of 15 items (α pre-test =.791, α post-test=.657). Those number were acceptable as the accepted value of Cronbach's alpha normally is 0.7; nevertheless, values above 0.6 are also accepted (Taber, 2018). The values between pre and post-tests are different because the effectiveness of simulation intervention changed participants' knowledge and attitude. In short, the knowledge test on sustainability is reliable, and the attitude test on sustainability is moderately acceptable.

6. Conclusions

This paper has described a simulation as a learning tool to cultivate knowledge and attitude to sustainability. With the quasi-experiment and pre-posttest one shot design, the group of 32 participants that completed the 4-week learning course with 'LCS in schools' simulation. At the end of course, it showed statistically significant increase in participants' knowledge on sustainability, change management to sustainability. Besides, their attitude to sustainability also grew after the course, implying the simulation is a potential training tool to cultivate sustainability mindset and awareness. Thanks to the simulation, educator learners perceived increased awareness and attitude towards sustainability, became more confident in the potential of pro-sustainability behaviours, and felt urgent for immediate action. The research has limit of small sample size. In further research, the authors would conduct more research in other courses to generalize the reliability and validity of simulation.

The 'Leading Change to Sustainability to schools' (Vietnam) might suppose that educators, teachers, school leaders are the target audiences for the simulation. However, the utility of this simulation as a training tool is quite extendable. The potential audience for the 'LCS in schools' simulation is indeed much broader. For example, people who are interested in sustainability, education for sustainable development would necessarily be equipped and supported the sustainability knowledge. Plus, the simulation also raises the attitude of participants as it seeks to cultivate sustainability mindset, and embrace sustainable practices provided in simulation. Thus, the simulation could be used with

it could also be accessed and integrated with modern teaching and learning methods such as eLearning, or hybrid learning.

Abstract

Universities play an important role in building a fairer society, within the principles of University Social Responsibility (USR), via the socio-environmental training of citizens. USR can be understood as an important strategy for the model of building a sustainable and fair society and involves a commitment to citizenship (Cruz-Ayuso and Santos, 2008) and also to its formation. Socio-environmental citizenship is about including the environmental field in the political sphere as a common good in order to form "ecological citizens", acting in favor of sustainable consumption, through the respect for the environment as a space for sociability (Costa and Theodosio, 2011). The objective of this article is to analyze the challenges of training for socio-environmental citizenship from the perspective of the university social responsibility in a Brazilian higher education institution of confessional origin. The methodology used was exploratory and descriptive in a case study, where documentary analyses were carried out in the La Salle University, a Catholic and private institution, of community and philanthropic nature, whose sponsor is a religious order called the Lasallian Brothers. The results of the analyses point to (i) evidence of practices where students need to act in favor of solutions to socio-environmental problems. It is evident that La Salle University provides opportunities for citizen education through practices in which knowledge from different areas finds challenges for its applicability in favor of socio-environmental solutions, especially in environments of scarcity; and (ii) the need to learn about democratic institutions in an integrated way with the curriculum as one of the ways to exercise socio-environmental citizenship, as well as the development of a critical and reflective capacity regarding the contradictions of society. Challenges were also highlighted to increase the number of extra-curricular projects where socio-environmental learning spaces deepen citizen education through the practice of finding solutions to contextualized socio-environmental problems. Universities play an important role in encouraging young people towards sustainable development through practical experiences of socio-environmental citizenship. "SDG+Target: 13.3".

Keywords: university social responsibility; education; socio-environmental citizenship

1. Introduction

The UN has established 17 Sustainable Development Goals (SDGs) within the 2030 Agenda, in order for all stakeholders to work towards socio-environmental issues and humanity's biggest problems (issues focusing on the planet, people, prosperity, peace and partnerships). Universities play an important role

socio-environmental training of citizens. USR can be understood as an important strategy for the model of building a sustainable and fair society and involves a commitment to citizenship (Cruz- Ayuso, Santos, 2008) and also to its formation. Socio-environmental citizenship is about including the environmental field in the political sphere as a common good in order to form "ecological citizens", acting in favor of sustainable consumption, through the respect for the environment as a space for sociability (Costa and Theodosio, 2011).Social responsibility must be based on the tripod people, community and common good. The relationship between these three key elements becomes essential to understand the concept of social responsibility (Lombardo-Bertolini, 2014). Solidarity is presented as a principle of Social Responsibility, because it deepens the interdependence between people and communities, contemplating socially ethical actions. Solidarity is a way of living, taking responsibility for interdependence with the Other, the Community and, finally, the Planet. The principle of subsidiarity focuses on the principle of aid, support, promotion, and development. Then it becomes necessary to recognize the social function of the private sector and the citizen, which is called to become an active part of the political and social reality of each country. (Lombardo-Bertolini, 2014).

University Social Responsibility (USC) can be understood as an important strategy for the model of building a sustainable and fair society and involves the commitment to citizenship (Cruz-Ayuso, Santos, 2008) and also with its formation. For Cruz-Ayuso and Santos (2008) the RSU must go beyond forming responsible citizens, contributing to economic, social, and cultural development and generating new knowledge and knowledge. The UW should be focused on a transformative orientation of society in the search for social justice, through the fight against social and economic vulnerability. This orientation is because universities are (or should be) interlocutors for a social dialogue, given their great capacity to create social capital networks. Cruz-Ayuso and Santos (2008) also criticize the quantitativeway in which universities are evaluated, favoring a competitive perspective. It is up to universities to take care not to depart from their social attribution through the search for a practical citizenship, whichconsists in the rescue of citizen protagonism in society, in its public sphere, which can occur through social re-institutionalization.

University social responsibility is involved in an education focused on socio-environmental citizenship in a critical and transformative way, through the articulation between theory and practice in favor of the transformation of the socio-environmental reality for the sustainability of life on the planet (Freire, 2004; Casanova, 2012).

The study of the agenda of socio-environmental citizenship is urgent due to the breaking of the interdependence between human beings and nature (Souza Santos, B., 2005). This is a reductionist conception of the world that can be transformed from an education aimed at a reflexive construction of an identity in order to provoke a transformation in society (Santos, M., 2005).

2. Methods

design in the context studied, providing an insight into the problem (Prodanov, Freitas, 2013). The empirical data refer to documentary research, consisting of internal archives to the institution as PDI (Institutional Development Plan), PPI (Institutional Pedagogical Project) and PPC (Pedagogical Project of Course) of two undergraduate courses (Administration and Psychology). Therefore, institutional documents from La Salle University were analyzed as analysis data for this case study. The case study is understood as an investigation that seeks a greater understanding of the phenomenon studied in a given specific context (Yin, 2001). The case investigated refers to La Salle University, Catholic, private, community like and philanthropic HEIs, whose maintainer consists of religious named Lassalist Brothers. In Brazil, the maintainer was founded in 1908, undergoing experience at various educational levels, becoming a University in 2017. The perspective focused on citizen education has always been based on lassalist educational philosophy.

At the end of the 19th century the first lassalist brothers arrived in Brazil. They have brought in important elements of citizenship training, as The RSU has been in the DNA of lassalist education since the founding of the first schools 300 years ago. St. John the Baptist of La Salle (1651 - 1719, France) not only taught by example, but left compendiums on how to structure, manage, teach, act in education for all, being declared the patron of all educators by Pope Pius XII. The mission of La Salle University is: to promote the integral and continuous formation of the person through teaching, of research and extension with innovation, excellence, for the sustainable development of society, according to Christian-Lassalist principles. Thus, the educational identity of La Salle University is marked in institutional culture with the characteristics of being a Catholic and Lassalist institution.

3. Results and Discussion

The principles and values of the Lassalist Educational Proposal are condensed into the expression "teaching well to live". In this maxim is that the citizen formation of La Salle University is expressed, because the good to live contemplates the ethical aspect and the practice of human and Christian virtues, since it encompasses the globality of the human being to be educated.

For the educational model, the University considers the following dimensions and competencies: anthropological (living between and with others), theological (transcending one's own existence), epistemological (creatively applying knowledge in interaction with oneself, with others and with reality), pedagogical (continuous educational process), ethical-moral (ethical conduct that guides actions to the well to live, acting with social responsibility and fraternal coexistence, fair and supportive), pastoral (experience of the evangelizing perspective, welcoming plurality and promoting interreligious, interracial and intercultural dialogue), politics (formation of people for the exercise of democratic citizenship, with critical and reflective capacity to interact significantly for the construction of a better society), ecological (awareness of the limits of the planet's natural resources), aesthetics (sensitivity to appreciate and transform the environment in which administrative (participation in the life and management of the Institution).

The following are evidence of citizen education in the Institutional Development Plan (PDI) and the

(2020-2025) and their Interpretation.

Table 1: Evidence of citizen training in documents at La Salle University

Excerpts	Docum.	Analysis
In accordance with the principles of St. John the Baptist of La Salle and the Institute of the Brothers of the Christian Schools, the Unilasalle assumes social responsibility to offer excellent teaching for professional training and for the construction of a humanizing society and ethical values, focusing on environmental education, the valorization of human rights and the ethnic-racial and indigenous conception.	PDI, p. 20	The pedagogical didactic organization of the University is socially responsible for offering teaching aimed at the transformation of society. One of the focuses of social responsibility is on environmental education, one of the bases for citizen education. It is analyzed that socio-environmental citizenship is envisioned in the document, as it provides for an articulation between theory and practice in favor of the transformation of the socio-environmental **reality (Freire, 2004; Casanova, 2012),** but not directly.
"provide the student with the knowledge, knowledge and professional **skills necessary for professional practice and citizenship**, based on scientific-technological, socio- historical and cultural foundations; [...] **promote the citizen education of students**, marked and constituted by the **experience of their knowledge in an interdisciplinary, valued and** integrated **way to the curriculum**; promote entrepreneurship and innovation to express the commitment to the socioeconomic development of the region; **propose actions of social and pastoral** responsibility, to assist and assist students and society, in unfavorable	PDI, p. 35	Policies guide that citizen education is inserted in the aspects of theoretical skills (knowledge and knowledge), as well as in the experience of this knowledge through practical actions. In this sense, it is analyzed that citizen education, from the formal point of view and as it is in policies (documentary evidence) points to learning aspects related to democratic institutions and also to learning for the effective exercise of citizenship **(Cruz-Ayuso, 2008).**
"The **political *dimension*** is sociocultural and aims at promoting an education committed to the formation of people for the **exercise of democratic citizenship**, with a cytic **and** reflective capacity to interact significantly and interpret messages, with a sense of building a better society.	PPI, p. 54	Consistent with the understanding of Gasca-Pliego and Olvera-García (2011), the political dimension is fostered at La Salle University, through the commitment to the exercise of democratic citizenship, where it aims to "build an informed, responsible and participatory citizenship that responds to injustice, unsustainability, violence and corruption" **(Gasca-Pliego; Olvera- García, 2011),** through critical and reflective capacity for a better society.
The humanistic perspective considers the values and principles that underlie the person's life, based on **Christian-lassalist references,** with emphasis on ethics, morals, otherness, compassion, solidarity, respect, charity and empathy.	PPI, p.55	The Christian-Lasallists references consider values that are consistent with the **understanding of Gasca-Pliego and Olvera-García (2011)**, in the sense of focusing on the university's primary objectives in function of social and human development.
The Pedagogical Course Project (PPC) [should also] highlight [...] concern about issues of **citizenship, ethics,** sociocultural diversity and human rights and ethnic-racial relations and environmental education.	PPI, p.60	All courses should show 'concern with the issues of citizenship, ethics [among others'. In this regard, it is questioned **how and** if citizen education really "systematically and rigorously incorporates situations of ethical learning and citizen education" **(Martínez-Martin, 2006),** as clarified by formal institutional documents.

By systematizing different university extension actions, which concern citizen education and USC, we perceive a profusion of actions that occur in different projects and formats and reach all our students. The actions involve students from different courses, teachers, technicians, political, religious, public and student organizations. Because of this myriad, we present them in a picture:

Table 2: Evidence of Citizen Training in Extension at La Salle University

	Share	***What***	***Observações***

1	Technosocial	It contains the Incubator of Solidarity Enterprises where it advises 4 recycling cooperatives (environments of scarcity and pooverty) to improve their management and emotional intelligence of the groups. Students carry out work on environmental education and social and environmental education.	120 garbage pickers 480 indirect beneficiaries 15 classes involved
2	University Pastoral	Solidarity, volunteering and food collection campaigns	231 Volunteers 300 people benefited 30 courses involved
3	La Salle University Project Includes	Letter course volunteers teach Portuguese Haitian and Colombian immigrants	Several immigrants benefited 47 students involved
4	University of Direction	Action of Pope Francis - team and 40 volunteers who do social actions	Various social actions 40 students involved
5	Bachelor's degree courses (4 to 6 years) have 120 hours of complementary hours	Students apply RSU projects and activities to prove hours	Technosocial, community service, extension courses, etc.
6	Extension Curricularization and Integrative Project - Bachelor's degree courses (4 to 6 years)	Extension projects are included in the curriculum of undergraduate courses, opportunistic when educating contact and intervention in needy communities, programs and social projects.	Teacher of each discipline guides students on actions that are consistent with the discipline. 67 disciplines
7	Free Legal Service	allow the population of the region access to legal guidance	Law students make an average of 430 annual visits to the community
8	Open University of the Third Age (UNATI)	Inclusive, adapted education, with emphasis on self-care, autonomy, health promotion and citizenship for the old.	254 elderly who benefited from 6900 annual activities (Data prior to the pandemic)
9	Assistance to undergraduate students	scholarships of studies in undergraduate courses of the Ministry of Educationand scholarships of Unilasalle	+ 1000 government grants + 200 health care grants
10	Psychopedagogical care	Rehabilitation, reeducation and social reintegration for People with Disabilities	+2900 calls
11	Inclusion of students with disabilities	Adequacy of classes, environment, monitoring for PCDs	+ 60 STUDENTS PCDs (People with Disabilities)
12	Follow-up for entry into the labor market	Students are informed of effective vacancies and internship vacancies and accompanied	+1500 contracts and + 110 companies
13	La Salle Health	-Psychological care at social prices - Psychological care to aggressors and victims of domestic violence (agreement with the forum) - Physiotherapy care - Nutrition care	Social and even free care to the community in different areas of health.
14	Program to Promote Access to the World of Work (Access to	systematic follow-up and workshops with content that can enhance the	900 visits to users in social vulnerability

15	SINE Project	Psychology trainees serve unemployed individually and collectively in internship	Group and individual care for the unemployed

In the 15 practical and/or extension actions evidenced in Chart 2, which refer to the USR actions of La Salle University, where there are learning spaces for socio-environmental citizen education to occur through practice.

The results of the analyses point to (i) evidence of practices where students need to act in favor of solutions to socio-environmental problems. It is evident that La Salle University provides opportunities for citizen education through practices in which knowledge from different areas finds challenges for its applicability in favor of socio-environmental solutions, especially in environments of scarcity; and (ii) the need to learn about democratic institutions in an integrated way with the curriculum as one of the ways to exercise socio-environmental citizenship, as well as the development of a critical and reflective capacity regarding the contradictions of society. Challenges were also highlighted to increase the number of extra-curricular projects where socio-environmental learning spaces deepen citizen education through the practice of finding solutions to contextualized socio-environmental problems. Universities play an important role in encouraging young people towards sustainable development through practical experiences of socio-environmental citizenship.

In the actions mentioned, socio-environmental citizen education meets the social realities where students need to act in favor of solving social problems. In this myriad of evidences, it is understood that La Salle University provides opportunities for citizen education through practice, where the specific knowledge of each area encounters challenges for its applicability in favor of solutions for the individual and collective, in environments of scarcity, agreeing with Cruz-Ayuso (2008).

In interpreting Martínez-Martin's (2006) understanding of actions in terms of citizen education, we understand that students are opportunistic to mobilize three types of training: deontological, because they can apply technical knowledge in real environments, with real people; citizen and civic education, learning in practice and human, personal and social formation by contacting with different situations and needs of society.

According to Martínez-Martin (2006), it is more common to find deontological training in universities, progressively commissioned by the formation of citizenship and civics and rarely, human, personal and social formation. The evidence indicates that, at La Salle University, human, personal and social education has the opportunity to be put into practice due to extension projects.

4. Conclusions

The objective of this article was to analyze the challenges of training for socio-environmental citizenship from the perspective of the university social responsibility in a Brazilian higher education institution of

act in favor of solutions to socio-environmental problems. It is evident that La Salle University provides opportunities for citizen education through practices in which knowledge from different areas finds challenges for its applicability in favor of socio-environmental solutions, especially in environments of scarcity; and (ii) the need to learn about democratic institutions in an integrated way with the curriculum as one of the ways to exercise socio-environmental citizenship, as well as the development of a critical and reflective capacity regarding the contradictions of society. Challenges were also highlighted to increase the number of extra-curricular projects where socio-environmental learning spaces deepen citizen education through the practice of finding solutions to contextualized socio-environmental problems. Universities play an important role in encouraging young people towards sustainable development through practical experiences of socio-environmental citizenship.

The analyses also indicated the importance of a context that welcomes and develops the critical and reflective capacity regarding the contradictions of society. Moreover, the humanistic perspective can provide opportunities for learning aimed at the search for social and human development. It is also observed the need to put into practice actions for citizenship, ethics, sociocultural diversity and human rights and ethnic-racial relations and environmental education.

When analyzing evidence of extensionist projects, it is observed that in the actions of USc there are learning spaces for socio-environmental citizen education through practice. In them, students know and deal with social realities, putting into practice the development of citizen education where the specific knowledge of each area encounters challenges for its applicability in favor of solutions for the individual and collective, in environments of scarcity. In this sense, the challenge is to maintain the projects in activity, in view of less support from public policies.

Developing social sustainability with circus-based methods

Emma Stenström[1], Andreas Skjönberg[2],

Abstract

Can circus-based methods develop trust between people in organizations? If so, how? This paper reports the results of a one-year-long research project in collaboration with the Swedish circus company Cirkus Cirkör, the Center for Arts, Business, and Culture at the Stockholm School of Economics Institute Research, and the educational organization Hyper Island.

The project aimed to explore if circus-based methods could be used to develop trust between people in different environments. Different methods were already in use, and new methods were invented in several interdisciplinary laboratories. Special attention was given to developing digital methods due to the pandemic. The result was a series of performance workshops.

As a next step, the performance workshops were tested in five different environments, covering various sectors: a government agency, a private corporation, higher education, a municipality, and a not-for-profit organization.

Interviews and surveys were conducted in all these different environments, and at the university, randomized control groups were used to measure and compare the effects.

The results are fascinating. Circus-based methods and performance workshops add imagination and creativity, hope and surprise, embodiment and entertainment. They can contribute to increasing trust and extending the mind. We conclude that the experiences indicate that trust can be fostered in the short term. Increased trust can potentially enhance social cohesion and sustainability.

Trust is experienced in different dimensions: physical, emotional, interpersonal, self-trust, cognitive- and affect-based. Circus becomes a method, a metaphor, and a mindset, an area of projection and enchantment. The performance workshops allow for embodied learning.

Previous studies have emphasized the psychological skills that can be enhanced: the ability to learn from failures, collaboration, vulnerability, focus, and attention, but we can also see the philosophical aspects. These kinds of circus-based performance workshops can shift how we relate to the world, create new horizons of knowledge, build communities, and, potentially, cultivate social change.

The project addresses several goals and targets. In general, it is goal 16 that is of particular interest. The paper builds on several theoretical strands, particularly circus-based methods and trust and quantitative

Keywords: Circus-based methods, Trust, Embodied learning, Resonance

1. Introduction

Trust is a topic that has been studied from a multitude of perspectives, including sociology, philosophy, economics, psychology, management, international relations, automation & computing, to name only a few. Most definitions revolve around expectations in a relationship (James, 2005; Mayer et al., 1995; Kydd, 2005; Rotter, 1980). According to Luhmann (2014), trust reduces the complexity of social systems, which is needed for people to function efficiently despite a very high amount of information regarding social cues and risks regarding personal stakes.

In this paper, trust is defined as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other party will perform a particular action necessary to the trustor, irrespective of the ability to monitor or control the party" (Mayer et al., 1995, p 712). According to the authors, trust has a complex foundation and is not to be regarded solely as an emotional state or tendency.

Trust is also a prerequisite for societies to function well in general. Robert Putnam (2000) wrote: "A society that relies on generalized reciprocity is more efficient than a distrustful society because money is more efficient than barter. Honesty and trust lubricate the inevitable frictions of social life (p. 135)." This is also the case within organizations. In Sweden, "trust- based governance" is proposed as the alternative to "new public management" in the public sector (Bringselius, 2017). Instead of relying on measurement and control, trust and judgment become cornerstones in this philosophy.

Trust is one of the critical capabilities and skills that must be developed on an individual, collective, and system level (Wamsler et al., 2020). Further, trust is linked to sustainability. It is a critical component in creating social cohesion, and social sustainability is essential to reaching the global goals for sustainable development, 2020).

Some argue that trust might be on the decline. The global communication firm Edelman has studied trust for over 20 years. Their latest publication, "Edelman Trust Barometer 2022," claims that the "world is ensnared in a vicious cycle of distrust, fueled by a growing lack of faith in media and government." A growing crisis of trust in governments and institutions is also supported by, among many, the World Economic Forum (Mantashyan, 2022) and the United Nations Department of Economic and Social Affairs (Perry, 2022). Flew (2019) argues that "the rise of populism worldwide can be seen as arising from a more general crisis of trust in social institutions" (p. 1).

In circus training, trust is a crucial factor. Several studies show the critical role of trust, how trust is one of the qualities often developed through circus training, and how that, in turn, can enhance social cohesion (Dubois et al., 2014). The pedagogical effectiveness is not limited to specific techniques but includes the development of an array of personal and social capabilities. Essential among these is the ability of participants to trust themselves and others (Bessone, 2017).

According to several scholars, participants will develop an array of personal, interpersonal, and social skills." Chief among these skills is that of trust; trusting oneself and trusting others are vital components

Circus has a long tradition of working with communities and training non-professionals in basic circus skills. There is a growing body of research on using those circus-based methods outside the artistic practice. Many studies focus on youth or social circuses. A social circus is a" form of non-professional circus education where the focus is on personal development, social inclusion and self-expression as opposed to the achievement of a high level of artistic technique" (Cadwell, 2018, p 22).

The findings from these studies can be used to help interpret our results, but we also notice a gap. Few studies focus on how circus-based methods can be used in settings other than among youth and underprivileged groups. This paper explores the effects of circus-based methods on organizational and professional development, particularly on trust and sustainability.

2. Research Process

For the research process, design thinking principles have been used. The process was divided into four phases.

The first phase identified current challenges in different workplaces through interviews and a literature review.

In the second phase, the focus was turned toward the circus practice. Qualitative interviews were conducted with circus artists and circus pedagogues. A semi-structured discussion guide was set up, which has been proven to be an efficient way to collect qualitative data regarding behavior, attitudes, and values (Britten, 95; Potter & Hepburn, 2005). The data from the qualitative interviews were analyzed through thematic analysis by systematically identifying, organizing, and clustering patterns of meaning (themes) across the data set. Additional interviews were conducted with organizations that have used circus-based methods and an invention of methods that circus artists had used.

Insights from the research were then processed in a series of co-creation sessions, with the working group containing artists, pedagogues, an administrator from the circus, representatives from education, foreign affairs, and a corporate organization. These workshops were held iteratively throughout the process. The outcomes were mainly physical exercises on developing trust and creating performance workshops for different settings.

The fourth and final step was the workshops conducted in a series of iterations between November 19, 2021, and May 8, 2022. After each workshop iteration, participants' feedback was captured in qualitative and quantitative data. The data were analyzed in the following co- creation workshops with the working group and concerning theories. 190 people participated in five settings: a government agency, a private corporation, an educational institution, a municipality, and a not-for-profit organization. The aim was not to compare the different settings but to test the workshop in different environments. In the educational background, a randomized control group was used so that half of the students participated in the circus workshop and half in a more ordinary cognitive-based seminar on trust, addressing the same topics, but not through circus-based methods.

All participants were asked to sign a consent form where they agreed for the authors to use their input following these critical regulations:

- All data were to be anonymized
- All were asked to read and agree to a privacy note
- All were informed that they have the right to change their mind about what the author does with their information and to withdraw from the research entirely at any point and for any reason.

Table 1: Research process

First step: Understanding the Problem	Second step: Discover	Third step: Define	Fourth step: Develop & Analyze
Aim			
To understand the problem, primary research was conducted together with a literature review.	To understand what makes trust building in circus an integrated part of working together, primary research was conducted with respondents who have 'circus' as their profession or have had connections to the circus in their professions.	To create solutions to build trust, insights from interviews, literature reviews, and workshops were integrated into a series of co-creation workshops.	To understand the solution's potential, shortcomings, and areas for further development, a series of workshops were developed and tested in iterative sessions with different target groups. Quantitative and qualitative surveys were conducted with all external participants in order to explore how trust can be created through circus-based methods.
Method			
Qualitative Interviews & Literature Review	Qualitative Interviews	Co-Creation Workshops	Online and Physical Workshops Quantitative & Qualitative Surveys
Number of participants

Guiding Focus Areas and Participants			
Challenges to trust in a business context: • 6 employees on different levels Challenges to trust on a societal level: • 8 local employees at embassies across Europe	Insights on the process of trust among circus acrobats: • 7 acrobats. All working professionally for more than 4 years Gather already developed methods for trust: • 4 circus pedagogues. All with at least 5 years' experience as pedagogues and some professional experience working as performing artists Understanding what makes the circus methods and its approach unique to actors from other fields: • 5 people who are working in organizations, municipalities and companies who have used circus in workshops	Assuring a circus perspective: • 4 circus pedagogues • 3 circus artists • 1 CC employee Assuring relevance to other fields: • 2 participants from the Swedish Ministry for Foreign Affairs • 2 participants from the agency Futurniture Facilitation and transfer of knowledge: • 2 members of the core group	From a government agency: • 10 participants from the Swedish Ministry for Foreign Affairs From business: • 82 participants from Allianz, a mix of team members and managers From education: • 68 participants from a global master program at Stockholm School of Economics From a municipality: • 22 participants from the municipality of Malmö in Sweden From a non-profit organization: • 8 participants from a community sewing atelier which offers educational opportunities to tailors with refugee backgrounds.

3. Results and Discussion

From the first iteration, with participants working in a government agency, there were indications of the workshops' ability to transfer the circus' approach to trust in a playful setting and through embodied learning. The potential was identified for examples from the circus to work as a projection tool for the participants to discuss sensitive topics often not addressed with colleagues. Especially the circus approach to failure, as an acknowledged part of the creation process, served as an effective tool for a mind shift in the perception of failure.

Several iterations were then conducted at the company Allianz Suisse. During these iterations, perceptions of personal connection, level of trust, and readiness to share concerning the other participants before and after the workshop were gathered.

and personal connection among the participants.

- 85.7% of the participants either agree or strongly agree with the statement that the workshop increased their trust in the other participants.
- 85.6% of the participants either agree or strongly agree with the statement that the workshop increased their readiness to express themselves more openly with the other participants.

The qualitative feedback indicates that the Circus' perspective on trust and collaboration served as the basis for discussions among colleagues.

Two workshops were carried out with master's students at the Stockholm School of Economics. Half the students were randomly assigned to an online circus workshop, and the other half to a cognitive, more traditional workshop. All students answered a survey before and after the workshops to measure if a sense of trust was increased.

Also, here the findings were validated.

- 69.4% either somewhat agree or strongly agree with the statement that the circus workshop increased their trust in the other participants.
- 57.3% either somewhat agree or strongly agree that the circus workshop increased their readiness to express themselves more openly with the other participants.

However, and this is important to notice, the other non-circus workshop received similar ratings, which indicates that development could also be a critical topic.

When assessing the qualitative feedback, the circus' methods and approaches are perceived to give new learnings regarding trust.

The last workshops have not been evaluated yet. Therefore we only have the (very positive) qualitative feedback to rely upon, not the quantitative.

To sum up, most of the participants in the performance workshops experienced an increased trust in the other participants.

Therefore, it seems like circus-based methods can increase the experience of trust. We discuss how in the following, using theories from previous studies of circus-based methods and trust.

Through an iterative, interdisciplinary process, we created performance workshops using circus as a method, a metaphor, and a mindset. Circus training can enhance trust-building in a physical, embodied way, for example, when participants collaborate and guide each other blindfolded. An example is a participant who said:

"The "blind" test and trusting the other to direct your way made the most impression on me."

Previous studies have also shown that training circus skills can change the modes of encountering others, fostering trust, collaboration, bodily knowledge, and interactions (Bolton 2004; Dubois et al. 2014; Spiegel

The circus metaphors in the workshop in the form of film clips and personal stories are experienced as solid and authentic and act as successful accelerators for authentic discussions among the participants. As a metaphor, the circus becomes an area for projection. A natural connection between trust and circus acrobats creates curiosity for the participants to engage in the workshop. Here is a voice from a participating student:

"Focusing on a non-business area and projecting it into our studies made the most impression on me.

Previous studies support this. Several scholars emphasize the "enchantment" element connected with the circus. Enchantment is" a state that embraces the potential to become otherwise" (Wilson 2016, p 2). Circus is a sort of 'enchantment' and surprise, unveiling meaning in" new forms of attachment to the world" (Bessone, 2017, p 656).

As a mindset, the participants picked up many different things from the circus: the importance of trust, learning from failures, deliberate practice, playfulness, etcetera. These could be transferred to their settings, or as one participant expressed it:

"Working together (well) is about collaboration, practice, practice. Practice and patience. More playfulness would be very good also in a formal context as you actually "perform" better because you have fun and try out new things."

Circus teaches participants 'that nothing is impossible, and that doubt and fear are to be examined and absorbed into positive action' (Bolton, 2004, p. 193). Circus techniques and performances can be used as resources for interpersonal trust instead of achieving a high level of artistic technique (Cadwell, 2018). The aim is to create a space 'where ideas can be shared without fear, opinions, and attitudes can be openly stated, and fruitful conversation can flourish and grow' (Bolton, 2004, p 204).

Digging deeper into the topic of trust, previous studies of circus training have noted that trust is developed physically and emotionally between each other and oneself. Even if it is not a risk to life, losing face is seen as a threat – and needs trust. Participants had to trust each other physically and emotionally - and trust themselves. One expressed it:

"Yes, I experienced trust in the sense that because they would make fun of me or judge me while balancing badly. ;) So I felt very comfortable and therefore trusted myself."

Trusting those around you and trusting in the safety of the situation is crucial, but until trust in

t. Still, until you take that first step, the participants cannot truly participate. There genuinely trust becomes about trusting oneself, trusting others, and others, and as several scholars have pointed out how circus training can enhance psychological skills in participants, for example:

"Results showed that mental skills such as confidence, concentration, energy management, and emotional management are considered integral to success in circus also reflected differences that exist between sports domains, such ability to embody emotions and connect with the audience." (Ross & Shapiro, 2017).

Others emphasize the ability to focus. "Circus is a continuous dialogue with the audience and the viewers

the proper energy level to the task at hand ng been associated with optimal performance experiences in movement sciences and sports psychology. (Filho et al., 2016). Attention was also a key feature in an earlier study we conducted on what circus training could bring to business students (Stenström, 2016).

Other psychological benefits include the ability to relate to others (Cadwell, 2018) and a reduction in emotional problems such as worry, nervousness, lack of confidence, and fearfulness. (Neave et al., 2020). Welby Altidor, former Executive Creative Director of Creations at Cirque du Soleil, further describes how circus skills can enhance creativity and courage (Altidor, 2017).

Circus builds on risk as a key component. Without something to risk, the trust would not be needed (Coleman, 1990; Deutsch, 1958; Jøsang and Presti, 2004; Molm, Takahashi & Peterson, 2000; Szerszynski, 1999). The link between risk and trust becomes even clearer through Robbins' (2016) reasoning that trust emerges under conditions of risk and uncertainty – conditions in which the outcome of matter 'Y' is unknown. Thus, risk and uncertainty are necessary conditions for trust. Or, to rephrase it, trust is a way to calculate how to deal with uncertainty and risk logically.

Risk in the circus plays a central part in the performance of the act, the performed danger, as performative risk. The audience's perceived risk in the performed circus act is what draws an audience to be amazed by "death-defying" acts.

Circus also has a history of embracing failures and learning from them. Ibañez (2018) argues that trying out something new offers us opportunities for growth and change, "but with those opportunities comes the risk of failure. While we intellectually understand that to grow, we must take chances and try things we cannot accomplish until the skill has been learned, it doesn't seem to help how we feel about failing." Failure can offer an opportunity for building trust through vulnerability when acknowledging failure. Failures also provide chances for development and learning new things if you learn from your mistakes. As two participants noted, independently:

"I was reminded that failure is necessary and good."

"Failure should be celebrated, as it offers the opportunity for something new."

The approach to failure in the circus plays a central role in trust building. Between acrobats, failure is the very start of each new learning curve. When an acrobat starts training a new trick with a partner or alone, failure is assumed. The process has similarities with reward-based learning (Palminteri et al., 2015), as, among acrobats, the failure is acknowledged and owned, thus not an indication of a breach of trust. This enables a more accurate reflection detached from the influences of emotions. Using this circus approach in training did not only support a mind shift regarding failure but also as an enabler for vulnerable and authentic conversations.

These conversations contributed to perceived reliability among the participants and fostered sustainable relationships built on interpersonal trust.

"What I take from the workshop is to give initial trust instead of being suspicious. Take a leap of faith, communicate, express doubts, and collaborate on the best solution together".

Among acrobats, acknowledging the failure, analyzing it, owning it, taking responsibility, and showing a change in the next training session builds trust. When acrobats examine the loss in several small steps, each involved party learns how the other(s) behave in situations of danger and stress. And, through the event of failure, each party learns about the other's (and own's) ability, benevolence, and integrity, resonating with Mayer, Davis & Schoorman's model (1995).

Faith in judgment and competence is also built by affect-based- and cognition-based trust elements. Affect-based trust plays a significant role as a starting point as the connection between the acrobats needs to be personal and authentic to withstand the challenges of training, failure, pain, and exhaustion. The characteristics of affect-based trust resonate with other researchers' findings (Lewicki & Bunker, 1995), involving individuals creating a common ground by understanding expectations on responsibilities. When affect-based trust is established, cognitive-based trust plays a prominent role. When there is a high stake (life or death/injury) investment, a person's actions play a more prominent role than the emotional connection.

A significant discussion in the co-creation workshops was what characterizes the circus, or as it was expressed:

"How do you "circusfy" a workshop?"

Is it the skills that characterize the circus? The objects? The aesthetics? The ethics? The attitude? Or, perhaps, a combination of all and more.

From the outside, an essential element was the instructors, who all came from the circus and acted as role models, showcasing the circus mindset. Capturing this circus mindset is not easy, but it has elements of an inclusive attitude, creativity, presence, physical intelligence, humor, surprises, social awareness, and care. During the co-creation workshops, it was, for example, often pointed out how important it is that everyone can participate and that nobody feels too uncomfortable or excluded.

In earlier studies, the role of the instructors has been pointed out. "The presence of soft skills among circus tutors essentially goes unnoticed. Much like plumbing, it only becomes a problem when it stops working. However, when a tutor lacks that ability, or when insufficient time is given to trust-building within the class setting, the efficacy of circus as a strategy for personal development falters." (Cadwell, 2018, p 28).

Another aspect that turned out to be important in co-creation was the space. After a few iterations, one of the artists came up with the idea to build boxes showing the different topics in the workshop: trust, failure, collaboration, etc. These boxes could then be used in different ways: to play with, to co-create a workshop around, to introduce oneself, to build a physical space, etc. The boxes created an experience and made the circus element stronger.

Space is also vital in a metaphorical sense. The space blocks everyday life out of the 'circus bubble.' It

educational or business settings – towards the 'new' rules and goals of the game. This opens opportunities for new experiences, perspectives, and relationships.

Space is not only physical but also emotional. The principles of the circus inspire a space where ideas, opinions, and attitudes can be openly stated, and fruitful conversation can flourish and grow, according to Bolton (2004). This was also incorporated in the performance workshops, where attention was given to designing workshops where participants would feel safe. Just like a trapeze artist need to ensure that the trapeze and crash mat is functional for them to feel secure enough to train, it is essential to assure that all participants are familiar with the used technology and the anchor points. It is necessary to set a transparent frame for open and honest conversations.

Objects, and the manipulation of objects, are other key features of the circus. According to research, incorporating objects can be one way to extend the mind (Paul Murphy, 2021). The workshops included everyday objects, apart from boxes, plastic bags or newspapers, feathers, and balls.

Others include movement and the body (Paul Murphy, 2021), which might be the most apparent element when using circus-based methods. "It is the physicalities, and corporeal relationship experienced rather than the narratives illustrated [in the creation process] that become the locus of transformation' (Spiegel, 2016, p 55). Those comparing circus with sports emphasize how circus arts are non-competitive and open up physical experiences for those who do not like to compete (Ross & Shapiro, 2017). Embodied learning is a crucial feature of circus training. Or, as one of the participants writes:

"I've learned a new thing, played, and had fun. I felt my body. Experienced focus (inner and out)."

This is in alignment with the sociologist Hartmut Rosa's concept of resonance. Circus art can support the participants' experiences of resonance, which in turn can help them restore their relationship with the world. Instead of appropriating the world, as is often taught in management education, art opens up for *experiencing* it in an unpredictable, uncontrollable way. The experience is embodied through the skin, breath, voice, gaze, and other bodily organs and senses (Rosa, 2019).

Many studies have observed the psychological effects of circus training, but as important are the philosophical ones of changing the relationship and becoming more responsive to the world. "Undermining bodily and emotional labeling and expanding empathy, the social circus has the potential to affect subjectivities and communities beyond the time and space of the workshop, to foster an 'ethics of becoming "more responsive" to the world' (Wilson 2016: 10).

The specificities of the circus foster" a challenge to habitual modes of relating, one that breaks with habits of thought and interaction, to open up new individual and collective horizons for future social and cultural development" (Spiegel 2016, p 64).

This is true for bringing in arts-based methods in general. Art can be used as a sensitizing experience, bringing unexplored bodily senses such as tactile and taste to the educational setting (cf. Küpers 2017, Gallos 2020). Artistic interventions, such as our circus workshops, can help to destabilize the participants' bodily positions and provide them with a sanctuary in the form of an alternative discourse or a new vista

Bessone (2017) shows, for example, how circus training enhances the opportunities to be surprised by 'others' and encounter them in ways that undermine reductive representations, and Wilson (2016) continues: "Emphasis on creativity also implies accepting failure and ambivalence, remaining attentive to unknown outcomes and unpredictable solutions – that is, working towards an 'ethics of attunement'" (Wilson 2016: 15). This is in line with Hartmut Rosa's idea of resonance. One participant expressed:

"The circus interlude was simply "refreshing" and "something different": in other words: "Sau gut ;-)." The topic "trust" is so enormously important, and also every partnership/marriage/etc. is based on trust. This feeling of trust releases enormous energies: you feel protected, sheltered, supported, and caught if something does not work out as desired".

An earlier study explores how circus skills can be integrated into academic subjects. The authors conclude that "three common ways students experience agency through the integration of circus practice and academic knowledge. First, students can build new knowledge from their domains of comfort into domains of discomfort. Second, combining embodied and academic knowledge expands student access to creative solutions, thereby expanding their knowledge horizons. Third, we notice that the collaboration inherent in the practice of circus arts enables community building, which, in turn, elicits the development of trust in new situations. We see each of these elements as foundational for social change." (Hoak, Funk, & Berkley, 2021, p 147)

Therefore, three elements might contribute to enhancing sustainability through circus training: entering domains of discomfort, combining different knowledge forms, including embodied learning, and the development of trust.

We are not the first ones to recognize the potential for the circus to become a site of pedagogy. Through a similar path, Wilson (2016) concludes:

"The peculiar meanings and roles acquired by trust in circus practices, where learning entails placing one's integrity and sometimes life in the hands of someone else, and where creation and performing rely on skills of 'bodily listening' and non-verbal communication; and an emphasis on creativity which praises and values the unexpected character of the outcomes of learning or creative processes, and enables to reframe behaviors otherwise classified as marginal, deviant, or pathological, as factors of diversity 'without the minus,' and even as resources for artistry and inventiveness. These features normalize destabilization within social circus spaces, turning them into significant sites of 'politics and pedagogy'" (Wilson 2016, p 6).

Circus performance workshops as "significant sites of politics and pedagogy." Now, that is an exciting thought – and a tentative conclusion.

4. Limitations

Although the findings are inspiring, there are some limitations regarding reaching the same engagement across different generations and aspects of time.

been tested with temporary groups of people, no findings are made on long terms implications on established teams.

2. Speaking openly about failure seems to strike different nerves among different targets. A senior target can connect it to experiences at work. These issues might not occur as frequently among a younger generation as there are indications that reflecting on failure is more common.

3. The workshop has shown limitations in terms of time; a workshop of 90-120 min can serve as an initial introduction to the topics. A continuous critique has been the workshop's short length, which ties in with the findings that time is needed to build trust.

5. Conclusions

After having created, through an interdisciplinary, iterative process, and tested a series of circus-based performance workshops in different environments, we can conclude that the experiences point to that trust can be fostered, at least in the short term. Increased trust can potentially enhance social cohesion and sustainability.

Trust is experienced in different dimensions: physical, emotional, interpersonal, self-trust, cognitive- and affect-based. Circus becomes a method, a metaphor, and a mindset, an area of projection and enchantment where we can become otherwise.

Many previous studies have emphasized the psychological skills that can be enhanced: the ability to learn from failures, collaboration, vulnerability, focus, and attention – and we note the same.

Among the crucial factors are the instructors, the physical and emotional space, and the objects used. Of particular importance is the fact that the performance workshops allow for embodied learning.

Finally, the philosophical aspects are at least as important as psychological skills. These kinds of performance workshops can, in the best of worlds, shift how we relate to the world, create new horizons of knowledge, build communities, and cultivate social change.

University Social Responsibility experiences in Higher Education: Engaged research in Kyoto University

Paola Sanoni[1], Fernando Palacio[2]

[1] *Jr. Associate Professor, Kyoto University, sanoni.paola.7n@kyoto-u.ac.jp*
[2]*(Former) Jr. Associate Professor, Kyoto University, dr.fernando.palacio@gmail.com*

Abstract

This study presents a selection of academic experiences based on the principle of institutional engaged research applied through the University Social Responsibility (USR) approach to several disciplines of Higher Education (HE) through participative projects to promote education through social action. These participative projects involved academic guidance and the application of students' knowledge integrating humanities, social sciences, natural sciences, engineering, medical, and life sciences to promote innovation and bring actual solutions to the social challenges of real communities targeting the members of the community as primary beneficiaries. These experiences were implemented as research projects locally and overseas, and they hold in common (1) their advocacy for contributing toward the accomplishment of SDGs focused on community development, and (2) their application of a participatory methodology at Kyoto University. This methodology appears engaging for the students, as it enhances the development of soft skills, and facilitates their social involvement through the fieldwork. Additionally, it challenges their creativity, fosters the use of their multi-language abilities and communication skills, and provides a unique opportunity for understanding some of the felt needs of society. Through these projects, HE institutions enact their USR engagements by emphasizing their community-based approach, highly relying on the cultural background, understanding, processing, and acceptance of the beneficiaries. As a result, the experience enhances the social sensitization of the students and promotes a positive and socially engaged attitude among future professionals. These experiences have also given the students a sense of empathy towards social needs in particular with the initiatives implemented in rural, isolated communities and communities in need or deprived of specific support such as understanding, or changing their perception of well-being.

Keywords: SDGs, USR, Social responsibility, higher education, sustainability

1. Introduction

Founded in 1897, Kyoto University is the second oldest national university in Japan. In the light of the multiple complex issues threatening the survival of humanity such as accelerated climate change, large-scale natural disasters, environmental degradation, and facing a post-pandemic scenario among many other global challenges. Kyoto University, as a socially engaged institution, actively promotes the discovery and development of practical solutions, it consistently shares not only its academic findings and progress but also engages with society at large in ways that allow for those contributions to be

Since its foundation, Kyoto University has constantly brought its academic developments to address social and environmental problems through concrete innovative solutions. Its historical commitment to academic freedom and the pursuit of a harmonious coexistence are pillars of its institutional identity. Its mission statement highlights the university's social engagement and responsibility promoted through cooperation with the local and global societies to disseminate the knowledge produced and guided by values that foster freedom and peace and to promote academic cooperation. This latter gains particular relevance with the advent of global initiatives at the heart of the United Nations such as the Goals of the Millennium, and its successor the United Nations Sustainable Development Goals (SDGs) have been received in the academic world as new opportunities for engagement and as channels to continue bringing the academic developments of the university to society.

Beyond offering a common language (Nhamo, and Mjimba, 2020), the SDGs have promoted an increased interest among scholars to overcome traditional approaches to academic contribution and to venture into more proactive, engaged, and down-to-earth kind of research (Mori, Fien, and Horne, 2019); while also promoting the development of new curricula and pedagogical advancements that bring the concepts of sustainability to the classroom (Alm, Melen, and Aggestam-Pontoppidan, 2021).

Within the higher education context, the concept of University Social Responsibility (USR) becomes central to understanding why and how universities embark on efforts beyond traditional education and research as a form to give back to society (Sawasdikosol, and Moral, 2009). There are several definitions in the literature, but for the purpose of this study, USR is defined as the shared responsibility of universities, understood as a wide-ranging and evolving concept whereby they contribute to social betterment by integrating their social responsibility policies in all spheres of academic life, hence into institutional management, teaching, research, services, and public activities (Shek, and Hollister, 2017).

A key feature of how the higher education sector functions in today's world relate to the drive universities feel to respond to social and environmental problems and to showcase those contributions in ways that the public can understand. In this sense, both the SDGs and the appearance and increasingly influential global university rankings are pushing universities to do their academic work in more engaged and participatory ways (De Iorio, Zampone, and Piccolo, 2022).

At this point, it is important to highlight that although USR and SDGs relate to each other in a number of ways due to the impact and reach of universities' contributions to achieving the SDGs, the USR framework of actions happens in a broader spectrum related to the life of universities (Castro et al., 2022). Thus, there could be a perception of overlapping the objectives and approach of USR and SDGs as both aim to contribute toward positive social and environmental changes. However, their essence, goals, audiences and stakeholders, methods, funding, and resources are different. For this reason, some universities would be in capability to do more and extend their mission from higher education toward an attitude of service and contribution to the global society.

Besides, there is a growing interest among HE institutions to include USR-oriented policies and activities in the way they function and engage with society. One of the most prestigious global associations is the

to promote a proactive mindset regarding how its academic contributions bring positive impacts to society, and of particular interest for this study is the promotion of engaged and participatory research focusing on universities' approaches to SDGs, and engagement with indigenous communities (Palacio, and Sadehvandi, 2022).

1.1 Purpose of the study

The purpose of this study is to present the methodology of ten projects as a selection of experiences in education and research at Kyoto University implemented with the common objectives of (1) promoting a collaborative and participative methodology for the students and (2) focusing on community members as the main beneficiaries. These particular characteristics enriched the interaction with the students and boosted their skill development in areas such as intercultural communication, and multidisciplinary collaboration, particularly during the implementation of fieldwork activities or online platform interaction. These projects were developed in a variety of disciplines of Higher Education (HE) and demonstrate how USR policies and practices are applied in the field and addressed to contribute toward the accomplishment of SDGs.

The methods applied on each project are widely supported by an organizational structure, institutional policies, and good practices of Kyoto University as a promoter of USR and its mission for contribution in society.

2. Methods

This study presents a list of 10 projects selected from a broad list of initiatives that contribute to the accomplishment of SDGs, in several disciplines and following the USR approach as each initiative aims for promoting a specific topic of development in the interaction of stakeholders promoted by social action. The study describes the methodology used by educators to promote a model of sustainable education including the participation of instructors, students, and community members in learning tasks. For this purpose, this study is based on empirical data collection research including personal in-depth interviews with the professors, researchers, or the students in charge of each project, processing of the existing data provided by them, and adding information through an independent data collection.

As a result, the study provides qualitative descriptions of the projects and the expectations of contributions of each project toward education for sustainability and accomplishment of SDGs in a participative and collaborative environment as well as a nurtured discussion about the supportive institutional framework that made possible such as initiatives. In some specific cases and due to the limitations of the COVID-19 pandemic, some practices were restricted (or addressed through an online approach), but the experimental component reminded as a principle toward a model of sustainable education that promotes a continuous

3. Results

Considering that universities are expected to create programs that raise ethical standards and encourage engaged citizenship among their graduates and researchers (Alzyoud, and Bani-Hani, 2015), and also that the USR approach overcomes the traditional philanthropy and fosters the idea of engaged academia and citizenship as a way to contribute to sustainable development (Vasilescu et al., 2010), the following projects represent clear examples of how USR can be put into action.

The projects selected for this study show examples of how engaged and participatory research can embed teaching technics that foster both learning and ownership among the students. At the same time, these projects show how each had incorporated USR aspects into its design and implementation in relation to addressing the SDGs, which was achieved by means of (1) promoting local initiatives to raise awareness and foster a change of attitudes aiming to address climate change and its impacts (SDG- 13: 13.3); (2) promoting inclusive quality education and lifelong opportunities (SDG4: 4.4, 4.7); (3) implementing international education through transborder collaborations oriented to the development of sustainable cities (SDG-11: 11.1;11.2;11.3); (4) building resilient infrastructure and upgrading the technological capabilities in developing countries (SDG-9: 9.3; 9.5); and (5) ensuring sustainable consumption and production patterns for emerging industries (SDG-12: 12.1).

It is important to highlight that as a result of the interactions produced through these projects, both learning and teaching of several disciplines are enhanced as a by-product of the process of sensitization for the students. This particular characteristic promotes a positive, empathetic, and more socially engaged attitude among future professionals creating a renewed interest and enhancing proactive responses from the beneficiaries to welcome initiatives that otherwise would not have existed.

During Kyoto University's presentation at the USRN Webinar Series on the university's approach to USR in the form of Engaged Research, projects with global, regional and local scope are presented in order to illustrate the wide reach and the multilevel nature of engagement of these projects and the diverse kind of initiatives that are taking place in order to foster and implement sustainable education (Table 1. List of USR projects selected for this study).

The diversity in the projects selected for the purpose of this study evidences the fact that the methodology used to address SDGs that includes the participation of students can be applied to several academic fields and yet bring similar positive outcomes. The following table offers an overview of the projects upon which this study was done and it refers to the name of the projects, the disciplines in which they were applied, the methodology each project used to be implemented, the level of impact, and the specific contributions to any particular SDG.

Table 1. *List of USR projects selected for this study (elaborated by authors).*

The following paragraphs offer a brief overview of each project and how each implemented its original teaching method to bridge engaged research with students' participation and external stakeholders contributing and benefiting from each project.

3.1 Projects with a global scope

The following projects were designed as platforms implemented on the first stages of the declaration of the COVID-19 pandemic between March and October 2020 and renewing their contents ever since. Students of undergraduate and postgraduate courses as well as professors and researchers were invited to collaborate and develop their materials of education and research in their areas of expertise or as a fieldwork experience and open it for the public domain.

(1) Corona Chronicles

The Center for Southeast Asian Studies (CSEAS) implemented the Corona Chronicles online platform, to gather the latest research findings from different countries and regions regarding the COVID-19 effects and its impact on individuals, communities, and nations. Also, the platform aims to gauge their reactions

provides accessible, clear, and concise commentary to a global readership, while it also welcomes research and articles from students sharing their views and experiences during fieldwork. To participate, students, researchers, and the public are invited to send their contributions in English, Japanese or their native language on a broad variety of topics that relate to the core topic of the platform which is COVID-19 effects and impact. Studies are welcome from individuals or groups, and results are shared publicly expecting to share information for readers from all over the world from a genuine source and open for discussion with participants from all over the world.

(2) Virtual Fields

Virtual Fields is a platform in a website, that provides video-teaching materials using aerial drone photography and Virtual Reality -or VR- images that capture forests, oceans, large-scale infrastructure construction sites, and experimental facilities of the university and of its partners overseas. The videos include university faculty expert commentary and guidance, for example showing how experiments are done in the field so students participating in the project can learn but also contribute in aspects like identifying facilities, developing the narratives and texts, carrying out technical production of the videos, etc.). Access to these materials is open to the public on the website named Kyoto University Virtual Fields. Virtual Fields is an initiative of Kyoto University ASEAN Center which is the international office of Kyoto University located in Bangkok and groups the efforts of education and research of Kyoto University in the region of Southeast Asia.

3.2 Projects with a regional scope

In the following projects, the students of undergraduate and postgraduate courses are invited to collaborate and develop their research in the areas as a fieldwork experience, sharing their knowledge and skills with the community in a collaborative experience.

(1) Road repair in Kenya

Road repair in Kenia is a project at the Graduate School of Engineering that aims to address the problems resulting from the fact that in Africa, 80% of the roads are dirt roads. The project engages with local people in the search for sustainable solutions in terms of repairing their own roads since they represent not only access and mobility but they represent life in itself, it is not only communications, but it is also trade, food, and family. The team works together with the communities by introducing simple methods to maintain existing infrastructure with the resources available, such as compact sandbags and using human labor, but more importantly, the project promotes a deep sense of ownership, independence, and self-reliance among the main beneficiaries and users. The project seeks to enhance awareness of the potential locals have to change their daily lives starting with the maintenance of their own roads which in the broad sense can contribute to overall development and wellbeing.

(2) Soil Rehabilitation in Sahel, West Africa

This project is an initiative of the Graduate School of Asian and African Area Studies. The project aims to problems arising from the devastation of lands, which in turn is worsening other problems such as food

the interest of the villages and creating conditions that may lead to civil war and terrorism. The project aims to rehabilitate soil that has been devasted as a consequence of people's habit of throwing garbage and leaving it unmanaged and to provide new conditions that can help prevent conflicts over agricultural and pastoral interests and increase social stability.

The research focuses on how certain plants grow in the garbage and how the soil and its nutrients change; with this as a base, the project seeks to foster a new mindset among the locals that consider ways to use garbage generated in the cities as a mean to restore the environment, improve urban hygiene, and to promote food security in rural villages.

(3) Grasscutters in Ghana

The Grasscutters in Ghana project at the Wildlife Research Center focuses on the grasscutter's genetic material in comparison to other well-studied rodents such as mice, the research seeks to identify their genetic advantageous traits, such as friendliness, high reproductive ability, intestine contents, and more.

This knowledge not only helps us understand what these animals eat, and when they eat, but also how to feed them better, while the project also fosters understanding among the locals that the grasscutters are also a rich and more sustainable source of protein, and that its human consumption can have important effects not only on a healthier diet but also in the environmental and economic impacts of related initiatives. This knowledge is also shared through several approaches to the local communities starting from elementary schools, as it is incorporated in relation to the importance of conserving the environment. This research is useful for increasing awareness of conservation and providing economic stability.

(4) ASEAN Network STI Coordinators project

This is an initiative of Kyoto University and the Japan-Association of Southeast Asian Nations (JAPAN-ASEAN) from the Science, Technology, and Innovation Platform (JASTIP) are leading an initiative to organize an online series of study group meetings for cultivating Science and Technology and Innovation (STI) coordinators between ASEAN and Japan in collaboration with Universiti Malaya, ASEAN Foundation, and the Committee on Science, Technology, and Innovation (COSTI) and the Sub-Committee on Science and Technology Infrastructure and Resources Development (SCIRD) and the ASEAN Secretariat.

This project started in 2020, and it aims to generate further awareness of cultivating professional Science, Technology, and Innovation (STI) coordinators in ASEAN and Japan. The project implemented a portal site to share results of joint efforts widely among the relevant ASEAN Community, Sectoral-Bodies, Universities, centers, networks, and committees to promote an active contribution of their joint efforts toward SDGs and the challenge of sustainability and develops periodical and tailored online events for collaborative work sharing their good practices and share the opportunities for institutional, funding and operative support among members in a diversity of research areas using an online co-learning mechanism of testing, analyzing, studying and reporting, together with a process of knowledge integration based on sharing common knowledge. These groups share their networks and knowledge resources as a main

sustainability from the past (industrial innovation, social contribution, etc); current (energy and environment, biodiversity and bioresources, disaster prevention) and future such as climate change, energy security, and the universal goal of humanity on this planet.

3.3 Projects with a local scope

These initiatives are designed to promote the participation of professors, researchers, students, and the community in general with the objective to raise awareness and sensitize the community members about specific topics related to sustainability. In these projects students of all ages and stages, workers from all industries, public in general, were welcome to share their thoughts and feelings rendering a platform for mutual understanding. All communications were designed to be developed in Japanese language as conceived for the local community, but they were so popular that up until now, some of the videos of their activities can be found subtitled to English and shared on social networks by participants.

(1) Online Public Lectures: #Stop and Think

The Online Public Lectures: #Stop and Think was set in the context of the Unit of Kyoto Initiatives for the Humanities and Social Sciences, established in 2018 as the implementing body of the Kyoto University-Designated National University Status and Concept "Future Form Transmission of Humanities and Social Sciences". This project advocates for the role humanities and social science have in real life, and the importance of speaking out about social issues. It promotes a vision with open solutions, without being confined to a narrow framework of expertise.

#Stop and Think lecture series started when the first state of emergency implemented in Japan due to COVID was lifted, proposing a post-corona society as a new opportunity. The project offers a virtual space to share the perspective of thinking broader and deeper about the future of society. In this series, 11 faculty members in the humanities and social sciences share their views on values and ways to rethink the future of our society through YouTube Live and Twitter Live, and anyone can watch them and participate in Q&A for free. These lectures delve into specialized topics presented by each faculty member who conveys suggestions for the society after COVID-19. Many affiliated researchers from the humanities have shared a sense of crisis about the transition of society under and after the pandemic.

(2) Everyone’s food loss revolution

This is a local project designed and implemented by the students with an SDGs focus, in the context of the umbrella project L’Ecole de Kyodai, at the Graduate School of Environmental Studies. L’Ecole de Kyodai is a group of students created to bridge academic initiatives with society by engaging with local communities, administrators, and the private sector, connecting transversely across academic fields, and encouraging student participation in the search for solutions to some key environmental problems.

This particular project reunites undergraduate and postgraduate students in a group of self-named Kyoto University Senior Rangers and it focuses on the organization of activities for raising awareness or promoting a revolution in the way we think about food, training to minimize the loss of food becoming waste mainly due to cultural assumptions that are based more on the notion of availability rather than

responsible consumption. The project engages with private enterprises in the organization of events such as workshops or exhibitions to raise awareness not only at the individual level but also at the institutional level, including for example hotels, restaurants, and other public and private institutions.

(3) My bottle dance: Sustainable use of plastics

This is another local project implemented by the students focused on raising awareness of the sustainable use of plastics. Major activities of the group include visits to facilities, events, and entities, such as gyms or sports fields, companies, recycling companies, local producers and exporters of agricultural products to educate different audiences about the impact's plastic bottles have on the environment. The students promote the use of reusable bottles among consumers, as well as the notion of refillable bottles among private companies. The awareness campaign is based on a dance that engages all audiences promoting the idea of using and reusing your own bottle at all times.

(4) Super SDGs sustainability talk: SDGs today and tomorrow

Students in this local project have created a YouTube Channel, where they share and disseminate short videos that aim at raising awareness to the general public regarding the SDGs, what they are and what they mean not only at the societal level, but also and more importantly at the individual level. The group promotes the notion that the SDGs are a personal responsibility, and that it is our own daily decisions that can have the biggest impact on how to achieve the goals proposed by the SDGs. The group proposes a new perspective of understanding the SDGs as a responsibility we all have to work for, where environmental friendliness is based on our daily decisions.

4. Discussion

The selected projects for this study implemented a participative methodology that provides plenty of opportunities for the students to implement their knowledge and their capacity to integrate the humanities, social sciences, natural sciences, engineering, medical, and life sciences to promote innovation and bring actual solutions to the challenges of real communities in a variety of scenarios, often addressing the approach of accomplishment of SDGs. Such contributions are developed as research projects that involve academic activities targeting the members of the community as primary beneficiaries. This methodology appears engaging for students, as it enhances their development of soft skills, encourages their social involvement through fieldwork, challenges their creativity and their use of multilanguage and communication skills, and it provides a unique opportunity for understanding the felt needs of society in challenging environments that may differ significantly from their surroundings at university or in their laboratories or classrooms.

4.1 Education for Sustainability

The concept of education for sustainability spurred from the pioneer discussions carried out during the United Nations Conference on the Human Environment in 1972 in Stockholm focused on environmental education and later education for sustainable development (Sterling, 2009). In this meeting, representatives from around the world agreed on the importance of fostering educational, informational,

Stockholm Declaration and Action Plan for the Human Environment, emphasizes the essential role of education in environmental matters for the younger generation as the basis for responsible behavior to be adopted by individuals, enterprises, and communities for protecting and improving the environment in its full human dimension (principle 19). This document also encourages governments to offer support for programs to develop and expand relevant knowledge (UN, 1972).

In 2022, the global challenges obliged the international organizations, governments, and all institutions with a prominent role in society to correspond with concrete measures in policy and practice to situations that jeopardize human security giving urgent relevance to the discussion about the concept of sustainability and what is feasible to do for reaching governments and the public. This situation brought to the table the topic of education for sustainability in critical scenarios as a top priority for public sensitization. Unfortunately, policy and practice do not seem to reach the point where the society is ready for the next pandemics, sanitary crisis, or further disruptions to respond with anything close to preparedness (Frutos et al, 2021). Then, education in the principles of sustainability, empathy, and compassion as a component of higher education and as a daily practice in society can possibly be the answer for bridging the barriers of inclusive education for sustainability.

For the purpose of this study, the authors consider the concept of education for sustainability based on the principle that there is an urgent need of spreading literacy and raise awareness about the current circumstances of critical aspects of the universe to ensure human survivability on earth. Regarding to the projects presented in this study, probably the most important issue is that all methods used in the projects are designed to guide the students to model themselves a criterion for sustainable options based on their own values and beliefs. Several authors point out the importance of an education that is oriented to promoting practical action revealing the transformative potential of students as agents of a sustainable future (Leal Filho et al, 2018), and the concept of sustainable education as a method for a sustainable transfer with an emphasis on “a model of education that aims to last” (Sterling, 2009). In that sense, the practice of fieldwork aims to imprint the knowledge on the students by doing and engaging with the members of the community that they aim to benefit.

4.2 Bridging USR and the SDGs

The concept of USR and the premises set by the SDGs explain why and how universities engage with society: both frameworks offer universities practical tools that help them overcome the traditional perception of universities as isolated or disconnected ivory towers. Each in its own way and through its own methods relates the institutional priorities of the university to the reality around them. Combined, these two offer universities a unique opportunity to understand each university’s own potential and power to produce impactful interventions, raise awareness about the holistic concept of social responsibility, and create synergies in the ways sustainable development can be achieved.

In the same path, there is a close connection between USR and the SDGs, as the role of the university and

actions. In other words, the understanding of USR among all members of a university shall go hand-in-hand with the decision-making process to implement academic projects aiming to contribute to the achievement of the SDGs and for sustainable development as a whole (Bokhari, 2017). At this point it is relevant to consider the potential impact of USR in four critical areas: organizational impact, cognitive impact, social impact, and educational impact. Organization impact refers to the university's social and environmental responsibility toward employees and the environment; cognitive impact relates to the responsibility for the purpose and use of the scientific and technical knowledge of the research activities. Social impact refers to the promotion of mutual learning toward social development; and educational impact through forming future citizens and their ability to participate of the development of society (Mohamed, 2015). All that said, it is the institutional decision of the university to focus on results with more emphasis on one or another, and prioritize.

The activation of the role of USR in sustainable development only works if the engagement is linked with a strong implementation mechanism (Bohkari, 2017). For this reason, the universities interested in such contributions will adopt institutional measures to ensure there is sufficient support to enhance the path to follow as the institutional values of an organization as principles that guide their operations are institutional decisions (Larran, and Andrades-Peña, 2017). Thus, it is possible to recognize the institutional engagement of universities with sustainable development in education from two perspectives: their structural values, and their operational principles. The perspective of the structural values of the organization refers to the self-declaration of the values of an institution in the mission, vision, strategic plans, and long-term goals. The operational perspective refers to the implementation of effective policies that promote the engagement of their different departments and units and facilitates their engagement with sustainable development.

4.3 USR Conceptual Structure

Meseguer-Sanchez proposes a conceptual structure of USR with 7 components: social, equity, healthy, wellbeing, environmental, economic, and human. This conceptual structure sets the bases of USR on the affirmation that "the university must train responsible citizens with their environment, creators of creative ideas and committed to helping solve social, economic and environmental issues" (Meseguer- Sanchez et al, 2020). In parallel views, Berman on his in his book "Educating for Social Responsibility" highlights specific considerations to help identify the essential conditions to ensure the provision of opportunities for the students to involve in projects of university social responsibility and mentions specific possibilities (Figure 1: Fostering opportunities for the implementation of USR; Berman, 1990:77). In that sense, each of the projects listed above challenged the capacity of the students to engage with the world, taking them to the fieldwork or learning in challenging environments Thus, the nature of the projects described above evidence the capacity of the education system at Kyoto University to enhance the development of social consciousness by promoting plenty of opportunities for the students to engage with global issues. According to Berman, the development of social consciousness is a process that does not just happen but is the result of a structure that combines knowledge about the world, experiences from society, and

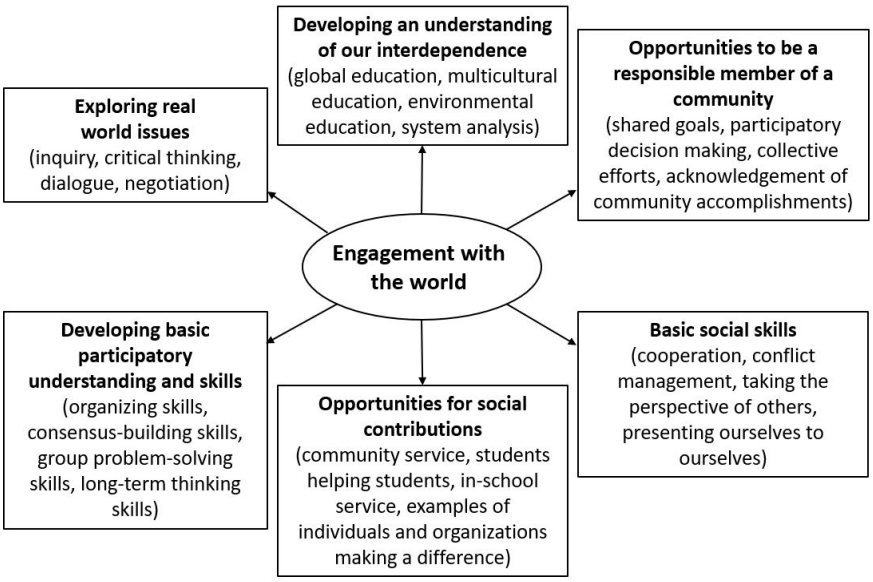

***Figure 1**. Fostering opportunities for the implementation of USR: The Development of Social Consciousness (Berman, 1990: 77).*

4.4 The role the SDGs on boosting education for sustainability

The SDGs provide a common framework of action, they also serve as a shared language that allows different stakeholders to share information in a way that is understandable and comparable even if the settings are completely different. For the higher education sector, in particular related to universities' commitment to USR, this represents a major opportunity in terms of enhancing their institutional commitment to educating for a sustainable future. However, such as universities' commitment to contribute to the accomplishment of the SDGs should be based on their own sense of responsibility to the future, and based on their own decision to produce research that is grounded on real problems with the intention to provide feasible solutions. This commitment must act as an institutional motivation to ensure the provision of an integral education that includes those problems in the curricula and offers opportunities for students' inclusion and participation.

From the perspective of the structural values of the organization, most universities affirm their institutional engagement and their commitment to its societal role in the declaration of their mission or vision as a way to secure sustainable institutional support by including social responsibility in their social, economic, and environmental dimensions (Bohkari, 2017; Larran, and Andrades-Peña, 2017). In that sense, Kyoto University's mission statement highlights the university's commitment to generating world-class knowledge based on high ethical standards through pure and applied research in the humanities, sciences, and technology. In the education field, the university is committed to the dissemination of diverse and high-quality knowledge that promotes independent and interactive learning and it strives to educate humane researchers and specialists with a sense of responsibility to the human and ecological communities. For this reason, all projects described in this study are widely supported by the institutional structure and policies of Kyoto University as a promoter of USR and its mission for contribution in

From the operational perspective, most universities are the owners of the policies they implement as long as they are aligned with their stakeholders such as the ministries that they are held by or their academic and administrative boards (Tetrevova, and Sabolova, 2010). Other organizations may use the concept as attractive without a system of reference that may relate purpose with results (Heras- Saizarbitoria, Urbieta, and Boiral, 2022). In this sense, it is essential that such policies are aligned toward embracing the interest of their members to build toward sustainable development from the perspective of higher education. Kyoto university's social responsibility is promoted through fostering cooperation with society at the local, regional and global levels to disseminate the knowledge produced, which is guided by values that foster freedom, peace, and academic cooperation. In terms of its governance, the University promotes the free development of learning, administrative independence, and institutional cooperation, in such a way that its administration conducts its duties with regard for the environment and respect for human rights.

Consequently, as it is an institutional decision of each university to define its own values and to establish its own policies in order to correspond with sustainable development through education and research, it is also a decision to establish its criterion to identify feasible opportunities that match its principles and to choose its partner institutions as not all opportunities for education in sustainability are for every university (Meseguer-Sanchez et al, 2020). From one side, universities are responsible for providing opportunities for their members to be involved and enhance the motivation for working with their communities but at the same time, universities also need to define institutional criteria to choose from the pool of opportunities considering their principles, priorities, capabilities, resources, and boundaries. For example, Kyoto University has a strict policy establishing that there is no collaboration in any manner, with military research. In accordance with the mission statement, all persons engaged in research at the University must understand that the research they individually choose to implement, and the outcomes of that research could potentially impact the future of global society. Thus, it is publicly stated that "no one at the University is permitted to be involved in military research that threatens those aims" (Kyoto University Mission Statement and basic policy on military research).

In a similar way, Kyoto University established a policy for Security Export Control to ensure that all exports of goods and technologies comply with the regulations of the Ministry of Economy, Trade and Industry of Japan (METI) which establishes that the equipment, materials, collaborative research and products derived are provisions of end-use control. Another policy regulates the proper use of research grants. All these policies are oriented to align the institutional principles, values, and interests in a unified criterion for choosing feasible opportunities, synergic partnerships, and for considerations about expected outcomes that align with the same criterion.

In parallel, some universities may have broader capacities and experience for sustaining a greater deal, as others may be at different stages of their institutional growth or have other assigned priorities. Thus, some universities may be able to adopt a holistic perspective and promote a broader view and readiness to implement, for example, challenging initiatives such as fieldwork.

4.5 Fieldwork as a method for participative sustainable higher education

their own learning process in higher education. Although it will depend on the institutional approach and organizational values to determine the limits of participation from immersive to participative avoiding intruding or invading the scenario of the community or beneficiaries which is another way of learning. From this point of view, Kyoto University has a long and strong tradition of international engagement and academic cooperation, with partners in many parts of the world in research about ethnology, ecology, geology, medicine, pharmaceutics and agriculture, flora, fauna, people, and culture. Over the last 60 years, the university has made an increasingly broad range of contributions to Africa. This is the reason why most of the fieldwork projects in this study have been selected from this region. The concept behind these research efforts has been the focus on finding the solutions to the various problems faced by the people. Throughout the experience, another valuable lesson learned is that the right attitude to approach collaboration is not to get something new to Africa or to the beneficiary communities but to learn from their daily practices and utilize that knowledge trying to improve their lives through interaction with community members. As a model of education for sustainability, the development of soft skills such as cross-cultural communication and negotiation are highly appreciated for the professional future in any field of work.

4.6 Sharing good practices and results as an institutional communication strategy

From another perspective, sharing good practices and results appears essential to promote the interest and commitment of the university for the purpose of reputation, but also to attract potential partners to the noble cause of working for the well-being of humanity and safety on the planet. Not doing so incurs into the perception of institutional neglect, and possibly loss of interest from their potential institutional partners or recruitment processes. In that sense, whilst it is true that most organizations in HE has shown their commitment to contributing to the accomplishment of SDGs, as the reinforcement of institutional engagement works as an internal call, each organization is independent of its policymaking. This means that there is only the willingness of the universities to work to make an effective contribution or not. There is no such measure of results or a mark to reach, only the noble intention to support a good purpose for the future of humanity for the further generations of researchers and students. Unfortunately, there are several organizations that point out their commitment to SDGs but their engagement is rarely found in their organizational operation (Heras-Saizarbitoria, Urbieta, and Boiral, 2022). In the end, each university is free to express its results either for attracting valuable partners for education, marketing and recruiting purposes or for external evaluation portrayed in university rankings. Again, it is an institutional decision.

5. Conclusion

The concept of education for sustainability may have changed its approaches over time but not its principles as education remind a prevalent aspect of responsible behavior for sustainable living. These days, still facing the struggles of the COVID-19 pandemic and the imminent effects of climate change reflected in floods, droughts, and other natural disasters, the global society may question the reasons why such discussions were not translated into preparedness before in order to face climate change, food security challenges, human security challenges, and the participation and inclusion of everyone through education

for the following generations as an extension of their role in society.

From the perspective of USR, the institutional engagement of universities relates to sustainable development in higher education from two perspectives: their structural values and their operational principles. From the structural values of the organization, it refers to including its institutional engagement in the statement of the mission, vision, strategic plans, and long-term goals including, for example, their commitment to the good of society. The operational perspective refers to the implementation of policies that promote and facilitate the engagement of their different departments with sustainable development and society. Additionally, it is necessary to establish institutional criteria for choosing the opportunities that align with both perspectives. For example, establishing boundaries to ally with certain partners, or establishing specific topics not to be involved. For example, reject potential partners working on military and weapons, or ban research on the development of technologies for such purposes. Later, it is relevant to consider finding effective ways of sharing the results with the intention to promote the essential interest and commitment of the university for the purpose of reputation, but also to attract potential partners to the noble cause of working for the well-being of humanity and safety in the planet. At this point, it is important to highlight that the methods applied on each project are widely supported by the organizational structure, institutional policies, and good practices of Kyoto University as a promoter of USR and its mission for contribution in society.

As well, universities have a role in boosting education for sustainability that goes beyond raising awareness and it is an institutional decision to transcend by reinforcing their commitment to future generations. This commitment must act as an institutional motivation to ensure the provision of a model of education with opportunities for the students to engage in the solution of real challenges. In these regards, Kyoto University fieldwork studies are conducted across various locations and fields. This method includes going to the actual place and living with the residents there for about 6 to 8 weeks. Then, the students are able to identify quite naturally the difficulties that people face and are more likely to propose feasible solutions. Often fieldworkers acquire a deep understanding of the local situation and their desire to solve those difficulties expands their research interests. Although, for the purpose of this study it was not possible to assess systematically the learning outcomes from each project.

Conclusively, the relationship between USR and SDGs has proven to work together for the good of higher education and for the good of society in terms of bringing alternative solutions to the felt social challenges of specific communities. Also, to promote an environment of social interaction for the students and their communities as a valuable experience for the development of their problem-solving and communication skills. As the SDGs provide a common framework of action, they also serve as a shared language that allows different stakeholders to share information in a way that is understandable and comparable even if the settings and the way universities work to contribute to them are completely different. For the higher education sector, in particular, the SDGs gain relevance in the context of the universities' commitment to USR. Thus, it can be argued that universities' best way to contribute to the SDGs lies in their forte: their academic power. It is up to each university to decide how to reflect in their actions their commitment to

opportunity to enhance their institutional commitment to a sustainable future for the global society.

5.1 Limitations of the study

This study describes how participatory methods for teaching contribute to a satisfactory learning experience, particularly in the context of institutional engagement of universities with the USR approach through addressing SDGs. Thus, two limitations to the generalization potential of the study should be noted. First, the empirical exploratory nature and the methodological approach used for this study rely on purposely selected projects that relate to their specific contexts. Some of these initiatives were conceptualized, at least in their initial stages, as either alternative methods of teaching and learning, as a response to a difficulty that finds an immediate response in applied science, or as an alternative to solve a particular problem in a given community. For this reason, this study can be considered as a showcase but not as a representative sample.

The second limitation is that the experience of the collaboration and synergies on the projects appears as more relevant than the methods applied for giving the students or the beneficiaries practical knowledge given that not all projects were originally designed for a specific contribution toward SDGs. For this reason, formal evaluations were left aside and the descriptions are focused on the opportunity to develop engagement with the world based on the opportunity and richness of the research experiences. Thus, another limitation of the study is related to the lack of identification of the learning outcomes. Unfortunately, for the purpose of this study, there was not a standardized method of assessment of the learning outcomes that enhances a comparison of the methods utilized by each project.

5.2 Future research

Further research may cover but is not limited to areas where USR can contribute with advancements of social implication such as (1) local and community approaches for improving access to elementary public services (such as education and health); (2) development of frameworks for collaboration with communities for actions and measurements to contain alimentary, health and climate disruptions (such as pandemics, providing refuge under critical circumstances, response to natural disasters, disaster mitigation, droughts, etc.); and (3) developing collaborative approaches to partner with other universities or higher education institutions located in different contexts that may bring alternative opportunities for participative teaching and learning as well as spaces for collaborations in the future.

Encouraging the diversity of cultural expression among students: What educational institutions can do
Violetta Petrova

Implications of collaborative design and strategies for sustainable behavior applied on design practice in remote emergency teaching
Karla Scherer, Ana Brum, Aguinaldo dos Santos and Adriano Heemann

ENCOURAGING THE DIVERSITY OF CULTURAL EXPRESSION AMONG STUDENTS: WHAT EDUCATIONAL INSTITUTIONS CAN DO

What is culture?

The culture of a society includes common values and beliefs learned from previous generations, adopted by current members of the society and passed on to future generations. These common values and beliefs provide us with behavioural patterns, norms and standards which regulate all the aspects of our lives and sets of ready-made solutions to everyday problems. These solutions turn out to be cultural models and frameworks of behaviour in different situations within a family, in an educational institution, at work, in public life etc. They determine the ways people feel about or interact with their parents, other members of their own society and other societies, employment and leisure, clothes they wear and food they eat. Cultural patterns are acquired through various social institutions, educational institutions being among them. Educating young people about their own culture is of great importance and has always been paid great attention to. However, in a global society it is necessary to educate young people about other global or local cultures and teach and promote respect for a wide variety of cultural expression in different forms and formats.

Formal culture studies

Objectives:

- teaching relevant culture-related content (depends on a students' major and on an academic subject) => doing business in a multicultural environment, promoting diversity in a work place, improving employee morale etc.
- teaching skills related to the content => holding discussions, proving your point of view, showing respect for the others' opinions etc.

Ways and methods:

- integrating culture-related topics into foreign language courses (General English, Business English, English for Professional Purposes)
- focusing on familiarizing students with the working cultures of other nations including information on decent working conditions, decent pay, fighting all types of discrimination and other issues
- choosing class activities to develop the required skills - making and presenting projects on the best practicies and procedures accepted in foreign and Russian companies, developing and implementing criteria for ranking the projects together with students, encouraging students' contributions to optional e-teaching materials

Outcomes:

- students get ideas for improving business processes in their own companies (E-shops, delivery business, beauty parlours, dance studios, confectionaries etc) or for their future careers
- students get info about decent companies for internship or future job placement
- graduates ask for better working conditions and pay when looking for jobs
- graduates develop ideas for improving corporate life when they get employed

Informal culture studies

Objectives:

- familiarizing students with the cultural heritage of the city / area where the university is located
- familiarizing students with the local cultures of their peers
- familiarizing students with the cultures of other nations
- organizing events to encourage students' creativity

Ways and methods:

- encouraging students to join the government subsidized programme "Pushkin card" - participants can get a fixed amount of money for visiting the city museums and theatres
- forming partnerships with the city theatres to get info about "students' days" (reduced prices for students) or free options to visit events and performances
- holding votes on choosing cultural events at the university (culture days, food festivals, concerts)
- encouraging the students' drama society and amateur performances

Implications of collaborative design and strategies for sustainable behavior applied on design practice in remote emergency teaching

INTRODUCTION

The context experienced during the Covid-19 pandemic by educational leaders revealed a need to restart some teaching activities with no previous preparation of competencies for remote practice. Supported by accumulated teaching experience, it was possible to offer a discipline of product design practice for undergraduate students remotely. The unprecedented nature of such activity allowed the approach of this study as a research action on collaborative design applied in remote teaching of product design guided by strategies for sustainable behavior in Brazil.

METHOD

The method chosen was the collaborative action research aiming to understand concepts, principles, guidelines, and practices by observing the results of a given phenomenon (DORST, 2011; SANTOS et al., 2018). The challenge proposed to the students consisted of designing solutions that resulted in the rational use of water or energy in bathing in social housing by applying Design for Sustainable Behavior strategies extracted from the model of Bhamra et al. (2011). The Double Diamond (DESIGN COUNCIL, 2005) was adopted as a design process model, which enables the alternation between divergent and convergent thinking.

RESULTS AND DISCUSSION

Six projects were designed and redesigned for refinement towards commercially viable solutions. The projects were included in an e-book on bathing habits.

CONCLUSION

Aspects stand out in the experience that point to guidelines for the construction of a methodology for the global teaching of design practice in a remote environment with a focus on collaborative design and solutions-oriented to more sustainable behaviours: a) the division of teams by competencies and meeting of groups with unprecedented training; b) the current theme proposed, encouraging the search for realistic and contemporary data experienced by the students; c) availability of reference material developed by the post-graduation, with substantial research to be used; d) constant feedback and insights from teachers; e) application of two project phases: design and redesign; f) mirrored feedback and involvement of students in the evaluative process.

A Blend of Indigenous and Non-indigenous Learning for Improved Educational Outcomes

Dr Lillykutty Abraham

St. Joseph's College (Autonomous), Bangalore, India

Abstract

The proposed paper would examine the resilience of the Mavilan tribe in the context of their enforced dehumanizing circumstances. Mavilan tribe settled in the Kannur and Kasaragod districts of Kerala, India, once was a nomadic people. With time, they were reduced to bonded agricultural laborers as the landlords encroached on their habitats. During this tenure, they were dehumanized as a result of many forms of torture including abject poverty and deprivation. Yet the tribe was resilient to withstand these hardships and they survived the traumatic experiences.

The data collected through the ethnographic method will be analyzed to explore their courage and resilient nature to survive. The art forms of the tribe, especially their dance and songs reflect their saga of suffering and their efforts of resistance. These art forms also will be discussed to see how they collectively cope with the external attempts to disturb their harmonious life.

The objective of the paper is to discuss the need to bridge the gap between the academic and the indigenous communities, or in other words, to strengthen the knowledge sharing between these two groups.

The indigenous communities may not have many 'educated' persons. But their learning from their natural setting and socio-cultural context is unique. These indigenous groups that safeguard Nature can contribute to the education of younger generations for a sustainable way of life. It is also important that the academic communities reach out to them for the exchange of knowledge and life lessons. Such an exchange can add value to the existing educational programs.

As the resources in their habitats have dwindled and they are not market-ready, they face challenges to eke out a living. This is where the educated communities must respond proactively. These communities need technical assistance to meet the demands of their ever-evolving context. A blend of both the indigenous and the non-indigenous lifestyle has to take place 'to end extreme poverty, reduce inequality, and protect the planet.'

The proposed paper relates to **SDG 4,** Quality Education for all**,** and **Target 4.5,** to ensure equal access to all levels of education for the indigenous peoples.

The paper relates to the theme of the conference as it would focus on the **sustainable lifestyle** of the Mavilan tribe. The fact that the tribe survived despite its hardships showcases its **courage and resilience**. The paper also will be delving into the **art forms** of the tribe. It shall also deal with their **right to a dignified life** instead of the deplorable conditions that some of them face now.

A description of *Aesthetic Knowing*'s role in Ecologies of Courage, followed by some Educational Considerations

Dr Ramsey Affifi[1], Ms Juliette Bertoldo[2]

[1]University of Edinburgh, Edinburgh, United Kingdom. [2]Maynooth University, Maynooth, Ireland

Abstract

The build up of atmospheric oxygen was highly toxic for early planetary life. However, because of the temporal and relational character of ecologies, what was once a disturbance had a chance to redeem itself through the dynamics it subsequently participated in. As contemporary ecological and social issues build upon and feed each other, we risk facing a build up of cowardice towards them. The more courage is needed, the harder it is to summon. The less we summon, the more those issues are exacerbated. It would seem we are stuck in a feedback loop, but the ecologies of courage and cowardice are more interconnected and shapeshifting than any simple vicious cycle.

In this paper, we explore how "aesthetic knowing" helps us perceive and respond to the complex relational nature of these shapeshifting dispositional ecologies. Aesthetic knowing is a felt evaluative response to quality of relationship, and as such it picks up on dimensions of persistence and change in ecological dynamics that analytic knowing deliberately prevents itself from seeing. In particular, aesthetic knowing evaluates the integration and disintegration of relationship. For example, a recurring idea from Aristotle through to today, considers beauty to be the perception of "unity in diversity." We can be spontaneously responsive to unity or to its dissolution in very complex systems because aesthetic knowing does not require that we pin down all the relevant components ahead of considering how they relate. The relationships appear as a whole, or Gestalt, with a sensed quality.

The ecology of courage fills with such evaluative experiences of beauty and ugliness, but what appears as integrated at one level or angle can appear disintegrative at another. If cowardice is to integrate into a beautiful ecology, how must we engage with it? How might fear oxygenate courage? Just as with analysis, perception of integration is empirical and therefore fallible. By keeping open threats against our current perceptions of integration, aesthetic knowing can provide not only conditions for new aesthetic experience, but also provide opportunities for cowardice to transform itself into courage. But because such openness means sometimes sitting with discord, this commitment itself requires courage. Such feedback loops are not tautological but constitutive of ecological dynamics, and far from being paralysing, they imply intervention points all across the system. We end with provocations for educators and educator culture. In that vein, this paper develops and connects several SDG themes that percolate disparately across many education systems, including Good Health and Well Being (+Target: 3.4) and Quality Education (+Target: 4.7), and concerned with ecological and social sustainability.

ARCHIPEDAGOGY: An Art Education for the Anthropocene

Dr Glenn Loughran

TU Dublin, Dublin, Ireland

Abstract

This paper sets out to explore a concept of educational subjectivity that is appropriate to the Anthropocene. Where the human capital subject of modern education remains the ideological blueprint for much educational theory and policy today, recent shifts towards Anthropocene thinking prompt a new conception of educational subjectivity that is entangled with the environment. At stake within this shift is a new understanding of agency within education that is neither radically autonomous nor infinitelyadaptable. Exploring the tensions between autonomy and adaptability, this paper considers how central concepts developed within island studies can be helpful for thinking about these shifts in artistic education. Utilising the postcolonial concept of archipelagic thinking to navigate the relation between 'locality' and 'world' this paper maps out the co-ordinates of an archipelagic art education for the Anthropocene, where the event of subjectivity shifts from the internal constructivist landscape of the student to the external, existential landscape of the world. This analysis will be supported by a practical artistic research project titled: What is an island?. The overarching aim of the project was to develop an artistic enquiry into the changing nature of islands within the political context of the Anthropocene. Whilst this journey was open ended and experimental, it also explored the formal characteristics of artistic research as an evental form of research that is appropriate to arts education and research in the Anthropocene. Since an event is always that which breaks with the normative situation, and, in this case survivalist modes of existence, this paper argues for an evental subjectivity in educational discourse. More concretely, the What is an Island project bridged the educational contexts of the BA in Visual Art on Sherkin Island and the MA in Art and Environment in the West Cork Archipelago (TU Dublin). Connecting these two points, the research performed a relational enquiry into the (a) values, tensions and concrete impact of visual arts education on isolated island communities (b) The development of artistic research and education platforms across island communities (c) The value of Archipelagic Thinking for educational subjectivity in the Anthropocene. To fully capture the scale of this project the following paper has been organized around three key structural dimensions: Site / Event / Sustainability. Through the Site of the project we gain an understanding of the educational contexts from which the project emerged. The second part of the paper will focus on the Evental quality of the research as it unfolded across three distinct archipelagic environments, from the West Cork Archipelago (2018) to The Galapagos Islands (2019) to the Virtual Environment (2020). Finally, the third section will focus on the Sustainable dimension of the research within Island communities and the potential for future orientations of archipelagic art education.

Dancing with the Other. A kinaesthetic and ethical shift from the egological to the ecological

Paul Moerman

Södertörn University, Stockholm, Sweden. University of Jyväskylä, Jyväskylä, Finland

Abstract

Dancing with the Other is a dance teaching method as well as the staging of a line of thinking arts *as* education, suggesting to reimagine education at large, and currently raved notions in educational contexts such as imagination, creativity, artistic expression and representation.

Education and dance are viewed and practiced as acts of transgression and as efforts to enter into dialogue with the social and natural world. The relevance and potential of dance as education are probed, as a mode of (kin)aesthetic experiencing in everyday school life, as well as a way of building ethically charged relationships infused by otherness, thus attending to issues of plurality and coexistence in a challenged global society begging for survival. A possible contribution by dance to an educational trajectory is suggested, reconsidering the human subject's very place in the world, notably an appeal prompting the Self to come into being by subjecting to what the world may be asking from one.

The theoretical lines of argument are informed by Gert Biesta's thinking on art as teaching, subject-ness and democracy in a world-oriented education, in dialogue with John Dewey's and Maxine Greene's thinking on art as experience, aesthetic literacy and aesthetic education, along with dance scholar Susan Stinson's stances on dance education and dancing as becoming.

The *Dancing with the Other* method is reviewed, along with an ongoing ethnographic field study, in which pre-service teachers describe and scrutinise their dance activities in the teaching and learning approach. The study results, discursively analysed, indicate that the participants experience dancing primarily in relational and existential terms of doing and undergoing, characterised by presence and concentration, intensified perception of movement, proximity, trust, communication, risk-taking and receptiveness for the unforeseen. Creating dance appears to be sensed in Dewey's terms of aesthetic experience, and the relations described may be understood as ethical in line with Hannah Arendt's and Emmanuel Levinas' thinking on freedom and otherness, fundamental in Biesta's and Greene's visions of education as a space for new beginnings.

This paper advocates the opening of spaces in education for the arts, letting dance remind us what education is about. The plead to reimagine education prompts a shift of focus from the autonomous, resilient Self and self-expression – the *egological* – to the necessity of being with others – the socio-*ecological* –, from predefined knowledge to the unpredictable, from conscious knowledge construction to pre-cognition, vulnerability and permeability through the senses, from education concerned with fulfilling universal ideas of humanism to education as a space for the unique human subject becoming, from education surrendering to market and competition to education as a space for encounters in plurality and coexistence in a precarious world calling upon us to act together for the entire planet's and mankind's survival – to let dance teach us what it is to be in the world, with others.

Keywords: Dance, art as experience, art as education, aesthetic literacy, aesthetic education, ethics in education, education and the existential.

Flying High, Falling Hard – Sustainability and presence in the performing arts

Professor Johanna Garpe, Assistant Professor Camilla Damkjaer

Stockholm University of the Arts, Stockholm, Sweden

Abstract

This presentation focuses on the possibility to create sustainability in an experience economy. Due to the development of digital overload combined with economic pressure, there is a heightened demand on humans' use of attention, requiring that we take in information through many channels constantly and simultaneously, quickly and with fast shifts. This also leads to changes in human perception and behaviour, developing a "click culture" where we shift our focus rapidly, moving from platform to platform in the need for instant gratification in terms of experiences. When we then attend or participate in the performing arts, there is no possibility to change channels or click on another device. What happens then?

In this conference we would like to present a research project, where we explore how to deal with this situation within the performing arts and performing arts education. One track within the project focuses on how we can draw on support practices, such as meditative practices, in order to develop a more critical and aware approach towards attention and sustainability. In this presentation, we will focus on how to challenge our own attention and aesthetic choices, training our capacity to refrain from quick delivery, to remain within slow and repetitive processes, and to stay open to other sense information and sense experiences.

One method within meditative practices focuses on how to pay attention to different sense inputs. But in the performing arts, the contemporary audience is mostly asked to use sight and hearing. However, historically, audiences have been absorbed in the event even through taste, touch and smell. This has been eliminated in the bourgeoise theatre, in order to control the audience's experience. But one may wonder if these other sensory aspects used historically did not only take away attention but also heightened attention. Today there is also a tendency to develop performing arts that to some extent mirrors the aesthetics of mediated practices, underlining the "4th wall" as a screen in new ways using digital technologies. At the same time, the very fundament of the performing arts is the live moment, involving embodied experiences with all senses, the possibility of improvisation and direct interaction. One question we would like to address is which role this live, sensory element can play in a sustainable relation to attention in the performing arts.

Reducing Carbon Footprints and Environmental Impact of Performing Arts Production

Assistant Professor Charlie Åström, Assistant Professor Gunilla Pettersson Thavelin, Assistant professor Anders Larsson

Stockholm University of the Arts, Stockholm, Sweden

Abstract

In this presentation, we would like to present the beginning of a research project that involves the whole Department of Performing Arts at Stockholm University of the Arts. The project addresses the question of how we can develop ways to produce performing arts with a reduced carbon footprint and reduced environmental impact in a time of climate crisis.

The performing arts build on the collaboration between many artistic practices, such as dramaturgy and play writing, light design, costume design, make up and wig design, production management, set design, sound design, technical coordination of production, theatre directing. Each of these practices involve different environmental parameters – ranging from the use of chemicals in make-up, to the use of electrical power for light and sound devices or fuel when transporting artists across the globe etc. In this project, we will explore which questions each of these practices encounter when we need to reduce the climate impact, and which methods we can develop in order to do so, collaboratively as well as within in each specialisation. This will help us develop the education of future artists within the field.

Historically, the performing arts have used the technologies available in each period of time to create live events for audiences. Today, we need to reconsider how we relate to the aesthetic traditions of the field as well as the historical and contemporary technologies we use in order to develop new approaches where live events with less climate impact can be produced. This also includes looking into all aspects the production process, increasing re-cycling of materials and adapting travel patterns.

Instead of looking at this necessary shift towards a more climate friendly way of producing as a form of reduction, we would like to focus on which new technologies that are possible and which new aesthetic forms, formats, and ways of collaborating across the globe, we can envision. To explore this in practice, the researchers involved in the project will "produce" a fictive performance and performance process, in which we will investigate how every practice involved can reduce their environmental impact, through which methods and with which aesthetic consequences and possibilities.

Rethinking Resilience in Environmental Education

Professor Carl Anders Safstrom[1], Dr Glenn Loughran[2]

[1]Centre for Public Education and Pedagogy, Maynooth University, Maynooth, Ireland. [2]TU Dublin, Dublin, Ireland

Abstract

Educational theory since Plato's *Republic* locates the subject in education within a pattern linking man and state. That is the resilient subject in educational theory appears at a particular location and for a particular reason; to be perfecting the state. Such location is, through Kantian theories of education, also from where the educated subject is perfecting nature's work. In the 20th Century, the resilient subject expanded through the theory of human capital, signifying a new relationship between education and society, where the modern autonomist subject increasingly merged with the neoliberal economy. Adaptability, market flexibility, and utility maximization are the economic pillars of a neo-liberal subjectivity that came to be defined in the late 20thcentury as 'the development- security nexus' that is, through the investment in human capital stock, such as skill and attributes, a subject can protect themselves against economic insecurity, against precarity[1]. Highlighting neoliberalism's capacity to appropriate its external antagonisms and resistances Julian Reid argues that the contemporary concept of resilience did not only develop out of classical neo-liberal subjectivity, defined here as human capital but also its alternative, oppositional discourse of sustainable development[2]. Emerging out an alignment between economic rationality and ecological rationality, this new survivalist subject is central to educational discourse and practice in the Anthropocene[3]. Within this context, we need to reconsider pedagogical subjectivity for the current age, one which is resistant to the appropriation of 'educational risk' into a paradigm of compliance and survival. Educational theory, therefore, needs to be formulated beyond perfecting either the state or nature, to relocate the subject in the reality of the everyday of life, to be able to move risk from basically meaning a threat to perfection, to an acknowledging of risk as an opening up of the present as autotelic, that is as itself carrying its aim, in the moment. Risk here, so we will conclude means to be able to unfold the present in ways that can't be foreseen, but which exactly, therefore, present the possibilities of new beginnings. This contribution will be discussing educational risk as central for the very understanding of education as such, by developing a sophistical practice of teaching.

The Potential of Arts-based Pedagogy to Face Imaginaries of the Anthropocene. A case study in Business School

Justine Buriller, Sylvain Bureau

ESCP Business School, Paris, France

Abstract

The Anthropocene is a term that highlights the consequences of human activity on their environment. Education in business school must adapt to this new reality. Far from being limited to the acquisition of formal knowledge or new skills, the Anthropocene calls for new narratives and imaginaries to deal with the ecological challenges. The pedagogical issue is not only to improve learning dynamics but also to help students in facing conflicting imaginaries. Drawing on the work of the philosopher Cornelius Castoriadis (1975), we consider that a "social imaginary" both constraints and enables our ways of thinking and acting. This social imaginary is formed by the ongoing tensions between a stable and established "instituted" imaginary, and the "instituting" imagination, that questions and transforms existing order, in an indeterminate and creative way. Based on this perspective, and leveraging the literature on arts-based pedagogy, we raise the following question: How can arts-based-pedagogy question instituted imaginaries of the Anthropocene? We explore the potential of a course – the Improbable seminar – taught since 2011 in a leading business school, that guides students to create artworks that challenge mainstream economic and societal models. The qualitative visual analysis of a sample of nine artworks, based on art history methods, discloses how they challenge the instituted imaginaries of the Anthropocene. We analyze the visual techniques that help the criticism to take shape and identify three types of criticism of the instituted imaginary in the artworks. This research provides three main contributions. First, we outline how artistic creations can embody the philosopher Castoriadis' theory of "social imaginary", by criticizing the instituted imaginary with different perspectives. Then we complement existing research on the power of visualization and materialization by exposing implicit imaginaries of the Anthropocene. Third, we contribute to arts-based pedagogy by discussing how creating artworks help developing students' critical thinking and imagination, through the implementation of a dialogical process. Students learn key competences and methods that can be used in the business world, and at the same time, they become more critical regarding mainstream economics. The subversive potential of art is leveraged to design new narratives that encourage students to reinvent values and rules, to shape more sustainable and desirable futures in the Anthropocene.

Children's Rights to make their Voices Heard and Listened to

Communication with politicians in and through art as sustainable development

Cecilia Ferm Almqvist, Linn Hentschel[2]

[1]*Södertörn University, cecilia.ferm.almqvist@sh.se*
[2]*Umeå University, linn.hentschel@umu.se*

Abstract

The UN Convention on the Rights of the Child (article 12) states that children have a right to make their voices heard, and to be listened to. Other policy documents at several levels underline the right to freedom of speech through various forms of expression, as well as young peoples' right to express themselves through art. To organize educational situations where children get the chance to develop and explore artistic forms of expression at the same time, in ways where their ideas and imaginations are taken care of in processes of dwelling, demands flexible and norm-challenging pedagogues. As an example of how Anthropocene discourses of education can be challenged, and instead involve children in sustainable collective engagement, a project where children communicate with politicians in and through art will state example for our contribution to the conference. The aim of the study presented is to explore and describe how 10 years old children's voices can be heard and listened to in communication with politicians regarding issues that engage them, from planet wealth to after school activities. The study is based on a project arranged by a municipal art school, performed in schools, where *Kulturverket,* a group of artists and pedagogues work together with children in different art expressions. To come close to the educational practice, interviews with *Kulturverket* was performed, and art works as well as presentations of the project in social media was gathered. The material was analysed in a phenomenological, hermeneutical manner. Hanna Arendt's theories regarding democracy were used to understand mutual becoming in communicative processes, and to deepen the understanding of aesthetical experience, Michel Dufrenne was related to as well. The results show the importance of identifying, treating, and expressing ideas in interplay with art, and how such educational situations demands imagination, collaboration, flexibility, openness, and courage. To make children's voices heard and listened to by politicians in and through art constitute one thread in a sustainable social network beyond the Anthropocene – towards "social sustainable development and courage, culture, art, and human rights".

Keywords: *Arts education, Children's rights, Education for Sustainable Development, Democracy, Arendt*

1. Introduction

The UN Convention on the Rights of the Child (article 12) states that children have a right to make their voices heard, and to be listened to (UN, 1989). Other articles in the UN convention as well as other international as well as national policy documents in Sweden, at several levels underline the right to freedom of speech through various forms of expression, as well as children's right to express themselves through art (Ferm Almqvist, 2016). This presentation focusses on how children´s arts expressions based on the UN convention are enabled by a culture organisation in collaboration with schools, where the children's creative work as outcomes are sent to their local politicians. The project can be seen as an example of striving for social sustainable development through arts within an educational context.

Sustainable development can be defined as meeting "the needs of the present without compromising the ability of future generations to meet their own needs" (SOU 2004, p. 20). The concept is grounded in a holistic view of human and societal needs, situations, and problems where economic, social, and environmental conditions and processes are seen as "interdependent and mutually reinforcing" (SOU 2004, p. 20). A sustainable society should be "permeated by democratic values" (p. 20), that allow for citizens to participate in influencing societal development with inspiration and ability to do so responsibly. The Swedish school curricula offer a multitude of expressions regarding democracy, and the right to express oneself and be listened to (Ferm Almqvist, 2016). For example, there are several postulates that underline students' rights to become themselves, to express themselves, to respect other students' opinions, to gain different kinds of knowledge, and that teaching should be in accordance with democratic principles. In the recently changed curricula for compulsory schools in Sweden (Skolverket, 2022, it is stated that the school should offer students possibilities to take responsibility, affect and evolve a personal approach to overarching and global environmental issues, through education on how societal functions and our way of living can adapt to fit sustainable development (see Skolverket, 2022, p. 8). From a philosophical perspective, it is possible to say that a society shapes the school, and hence, the school shapes the future, implying that a perspective of sustainable development should be apparent in education in all forms, subjects, and levels (Jonsson, et al., 2012).

In an educational context, UNESCO has set the ground for the field of education for sustainable development (ESD) (2020). EDS accommodates growing sustainability challenges by enabling learners' (in all ages) knowledge production and agency towards societal transformation focussing on sustainable development. They emphasise that ESD is a lifelong learning process (UNESCO, 2022). National policy states that ESD in Sweden should strive towards that the

starting with a holistic view on human and societal needs, prerequisites, and problems (SOU, 2004). Since this presentation is based on an investigation of an arts project within a school context, we focus on how art in education and children´s rights can play a role in education for sustainable development.

Earlier research on children's rights in arts education show the importance of not only acknowledging children´s rights to express themselves, but also our responsibility to listen and encourage action based on children's expressions. For example, we may turn to Quinn (2010) explaining that for children to participate in influencing societal development, they need both a will and the actual possibility to change praxis. In Quinn's example, students were given the possibility to share thoughts on what they wanted to change in their school, which led to an art project where the students created their own school uniforms and sending in a petition on the rules on the school´s dress code, resulting in that their school management change the dress policy. As Quinn tells, this can be seen as an example of how an art-based project can lead to new understandings and create change. Quinn's emphasis on making children's rights to have their opinions heard and acted on are like Aspán & Balldin (2017), explaining that if children's rights to voice and express their opinions are to be meaningful in a democratic society, we must acknowledge and build on children´s interests and creativity.

Aspán & Balldin (2017) emphasises that there are certain aspects specifically relevant for teachers in projects focussing on children's rights in arts education, that need to be considered. According to Aspán & Balldin, it is of importance that teachers treat knowledge production in arts education as co-created between them and their students. Other collaborative aspects between teachers and students in similar settings are also highlighted by Illeris (2017), in her call to use art education “a symbolic place where teachers and students can experiment together with how to live our lives in more sustainable and collective ways entangling and intertwining environmental, social and mental ecologies of being” (p. 14). Moving further on teachers involved in arts education, Aspán & Balldin (2017) recommend avoid making decisions of *what* creative situations should involve or where it *could* or *should* lead. Instead, teachers should be open to children's opinions in the creative process, and as mentioned above, allowing the children to act on their interests and creativity. Ferm Almqvist & Hentschel (2021) also points to teachers' responsibilities in arts (music) education in relation to reinforcing social sustainability. Teachers should strive to create “a normative foundation for practical social change and sustainable development” (p. 109), that enables all students to feel entitled to participate in (musical) activities that allows them to develop their (musical) skills, and “recognize themselves through creative and constructive work” (p. 109). This could contribute to social sustainable development within arts (music) education. Another example that takes music (and poetry) as a starting point

school contributes to sustainable social change. The project resulted in a public performance aiming to create a further need for reflection on social sustainability. Dahlbäck & Schmidt describe how the project could be seen as an example of how to enable change on a more long-term basis, as the outcomes of such a project – participation in cultural events (both as performers and audience) could lead to increased life quality and function as an option to material consumption. The researchers underline the importance of developing these types of projects as permanent school activities.

As a way of understanding "how recent currents in art education can contribute to the development of environmental sustainability as a central perspective in the field", (Illeris 2012, p. 80) presents an epistemological a genealogical platform collected within the concept art education for sustainable development (AESD). Illeris (2012) also highlights that "(...) the most important requirement for AESD is not to work with pedagogy and ecology as themes but to embody pedagogy and ecology as open-ended, explorative, pragmatic, and playful modes of being and acting" (p. 14). We hope that our presentation can add to the research field of AESD.

To consider children's ideas as a starting point for societal change can be seen as a way of challenging the Anthropocene. The phenomenon of the Anthropocene is often defined as demonstrating unsustainable qualities of ecological, cultural, and social human relationships, and is a growing issue within the field of ESD (Fedosejeva et al., 2018). Fedosejeva et al. underline the call and need for research focusing on holistic understandings of sustainability in ESD, since it enables possibilities for change, to develop new understandings and perspectives in education. Furu et al (2021) also emphasize the need for holistic perspectives connected to sustainability in education and draws on the importance of holistic learning processes as contributing to reflection and discussion of value, knowledge, and skills. Furu et al.'s investigation of a multimodal storytelling project (including arts) in teacher education shows the potential to enforce what they label a more child-centered approach. In line with Jonsson et al. (2012) who state that; ". . . education for sustainable development should start in the life- worlds of the children" (p. 95), this presentation takes life experiences of 10-11years old children involved in arts education as a starting point. The aim of the study presented is to explore and describe how 10 years old children's voices can be heard and listened to in aesthetic communication with politicians regarding issues that engage them, from planet wealth to after school activities. The study is based on a project arranged by a municipal art school, performed in schools, financed by *The General Heritage Fond* and *Umeå Munipicality* called "Alla har rätt" [Everyone is/has right/s] in Sweden. A well-established municipal organisation in Umeå, *Kulturverket [The Culture Service],* has performed artistic projects of diverse kinds during fifteen years, based on the statement: "Children tell the professionals what to do" (Ferm Thorgersen &

the children, in relation to a chosen article in the convention through their specific artistic specialities. The working method was based on a "relay model" where the projects ideas and artworks were passed around as a "baton" in between the children and the artists-pedagogues. The ambition of the current project was to contribute to understandings of the UN Convention on the rights of the child, which since 2019 is statutory in Sweden. The goals for the whole three-year project were formulated by *Kulturverket* as follows:

- To strengthen knowledge about Children's rights
- To ensure that children from different parts of the city meet and work creatively based on the UN Convention on the Children's rights of the child, aiming to create relations and counteract segregation
- Increase children's knowledge regarding their democratic rights
- Give increased space for children's voices in public spaces
- Strengthen children's participation in society

One part project, which makes the base for this presentation, was the "politician-project" where one poet-pedagogue from *Kulturverket* worked with four classes, with the intention to let the children identify, treat, express, and communicate messages to powerful people in and through art, in the form of post-cards.

2. Methods and theory

To come close to the educational practice, interviews with a poet and pedagogue employed by *Kulturverket* was performed about the philosophies behind, as well as the planning, performance, and evaluation of the politician project (Kvale & Brinkman, 2009). In addition, complementary written communication was performed via e-mail (van Manen, 1990). The post-cards created by the involved children were available through *Kulturverket's* internal Google Drive. Photos and text concerning the project were also mediated through social media, which constituted one part of the generated material. The interview was transcribed verbatim. Written as well as visual material were analysed in a phenomenological, hermeneutical, and arts -based manner (Barone & Eisner, 2012; van Manen, 2002).

Further, to be able to understand how children's voices can be heard and listened to in aesthetic communication, Hanna Arendt's theories regarding democracy was used as well as Michel Dufrenne's theories of aesthetic experience. A basic statement for Arendt's view of political action, is that is an actualisation of a "who", dedicated to hope, rather than upon an implausible law (Kristeva, 2001). Humans must recognize the becoming of "who" inside themselves where

(1978) relieved in the plurality of the world, in the common sense, where thought and action are interrelated. The “who” is although never a solitary self, instead human becoming takes place in action and speech with others. Arendt (2002/1961) underlines that in the common place, the political space, human beings meet to try out, sharpening and equal views and standpoints, at the same time as they create the specific public square. The who manifest oneself in its ”dynamic exceptionalness that could not help blossoming before the multitude of other people . . . who receive and interpret the acts of each newcomer by implicitly asking him the question, ‘Who are you?’” (Kristeva, 2001, p. 173). The “who” is intertwined with nature, society and historical narratives through creative action, and the “essence” of the who is not possible to state only when life departs, through the story that is left. Hence, to express oneself, share one’s opinions and be listened to, becomes a crucial part of citizenship (Arendt, 1998).

According to Kristeva (2001) Arendt’s main goal is to “preserve the freedom of the “who” at the heart of an optimal political plurality (p. 181), which she labels as “space of appearance” and “political action” that affords dangerous freedom of bounds with other people (Arendt, 1998).

Inviting children to identify, treat and express their ideas in interplay with artistic forms of expression constitute a place for dwelling as aesthetic experience. That is where the aesthetic sensation (noesis) makes the aesthetic ”object” (noema) complete. According to Dufrenne (1973) presence, representation and imagination, reflection and emotions together constitute aesthetic experience. Based on a phenomenological way of thinking where human beings are interwoven in presence where meaning is grasped as something that touches and engages, and where significance appears before human understanding of things. Meaning must traverse through the body, as it exists immanent in perception, in the ”sensuous”. That’s why contemplation, or present reflection, becomes important for understanding. The weight of representation and imagination concerns going from the lived to the thought, from the presented to the re-presented. Imaginations and phantasy contribute to transcendence, which demands a view of body and mind. In other words, it becomes crucial to go beyond the directly experienced, and instead view the world as it opens itself. Imagination demands a specific engagement, a lived body and transcendence, through closeness and distance in interplay. Generally, the function of reflection and emotions in sensation, it can be underlined that the first is needed for ability to understand significance; ”To undo its appearance to understand its law” (p. 370). The latter does not mean that to go back to what was presented in presence, but emotion is seen as something that relates to a specific quality that makes the ”object” states its intimacy, and the representation becomes ”something else”. Emotions contribute to aesthetic experience on a deeper level, to experience the hidden, and the sublime. Dufrenne (1973) underlines that strangeness and challenges contributes to deepening, to let oneself become surprised and taken; the world must continually

pedagogues, and politicians.

3. Results and Discussion

The results show the importance of identifying, treating, and expressing ideas in interplay with art, and how such educational situations demands imagination, collaboration, flexibility, openness, and courage. The "politician project" that constituted a part of the larger project "Everyone is/has right" described above aimed to letting 10-11-year-old children, four classes at two different schools, be heard by politicians through creating postcards mediating the children's identified, and treated desires for the future. A poet and pedagogue employed at *Kulturverket* was the main responsible person for the project, which now and then was questioned by his colleagues. All following citations in the result derives from him. The project leans on a strong idea that every child in the municipality should be offered to express themselves and communicate in and through artistic forms of expressions, according to Arendt (1998) a crucial part of citizenship, not least to grasp and encourage the once "who had never come to think about to write a poem". *Kulturverket* label this as they "hit" the schools and children, opposed how voluntary (paid for, mostly parent-driven) activities work. "We just drive there and 'hit' them, they don't have a choice, in a good way". Another starting point, or impetus, is that two different classes, where the children don't know each other since before, shall meet, and in this politician project the two classes share their postcards with each-other, (literally), before the about hundred postcards are given to the politicians, and take each-other's messages into account, share meanings, and become themselves in plurality, to speak with Arendt.

Figure 1. *No homework, we need our spare-time.*

When the poet-pedagogue arrives to the classroom he talks about the Children's rights convention, to encourage a debate, where the children are encouraged to make their voices heard in plurality. They´re asked if they know which rights they have. They talk for example about the right to privacy, and the poet-pedagogue talks about diaries, and connects to poetry, as a form of diary. They also talk about that they have the right to be protected from violence and harassment, and that it can lead to that their parents can have a need to have a look in their devices. "So, then it becomes an exciting debate. Because two views are set up towards each other". The poet-pedagogue expresses that he wished he had even more time and space for argumentation, rhetoric, and debate in the project, as that is viewed as healthy, if is done in non-hectic and not so sensitive ways. Then they work further on with article 12 and 13, the right to make once voice heard, and freedom of speech. Then they get a paper where they are to answer a couple of "Who are you"-questions as "What do you want to tell a powerful person?" These starting points can be seen as important aspects of political action, actualising the "who" in line with the thinking of Arendt (1998). At the same time, it becomes evident that persons in power are distant from a child's perspective, which influence the character of the messages. "They think it is a list of wishes to Sancta Claus. And that is a bit fun". The children are not clear about what is possible to wish, or demand. Some want to have more time to train Ice-hockey, while many want the

is issues within the municipality, that these politicians can influence, and he walks around among the children and asks “Who are you-questions” to help them identify their ideas and desires, for example regarding how sports-equipment could be more available, even for poor people. The children become engaged, they start processes of becoming “who's” (cf. Arendt, 1998) in relation to the poet pedagogue, and each-other. Each session is two hours, and the first out of two ends with formulated messages, based on insights in children’s rights.

***Figure 2**. Every child has the right to speak to someone.*

The aim of the second session was to make meaning and deepening ideas in interplay with crating artistic post-cards. They get the question, “If an avatar was the spoke person for children, what would it be like?” Hence, the post-cards were to include an avatar, imagined and created by the individual child, who tells the message, verbally, or in the form of a poster. Most often the spoke persons were related to the message, to deepen the message, a process of identifying and investigating their ideas in relation to art as a form of expression. The children needed to be present, to use earlier experience as well as imaginations, to connect to their feelings as well as reflection, which according to Dufrenne (1973) is what characterise aesthetic experience. The activities caused high sound levels, that on the one hand concerned the poet pedagogue (as he feels the reactions of the class teachers), but he also viewed it as a sign of creativity, and a part of making one’s voice heard, starting with the discussions regarding the children’s rights

this"? The atmosphere in the classroom develops through the artistic workshops where the children cut and paste, like a creative workroom. "I think it is awesome that it becomes a creative activity".

Figure 3 *More Geography in school.*

The poet-pedagogue's vision, which he had to convince some of his colleagues about, was that the postcards were seen as artistic wholes, that the politicians had to be open for and experience aesthetically (Dufrenne, 1971). Some of the colleagues thought that the messages should be formed in ways that the politicians could easily understand and internalize, like proposals. "But they are so full of fantasy some of them, then something disappears". The poet-pedagogue underlines that something happens, when the children treat their ideas and express them in holistic ways: "We have to save the planet…and then – a square-formed hat". From a phenomenological perspective where human beings are seen as interwoven in presence where meaning is grasped as something that touches and engages, and where significance appears before human understanding of things, it becomes crucial to offer these possibilities to children. As Dufrenne (1973) underlines, meaning must traverse through the body, as it exists immanent in perception. Without the visual expressions, the messages get emotion-less, the poet- pedagogue continues. "Some of them has been angry when they made the cards, they "teared out" their characters, and you can see *how* they drew, how they spelled, and some of them really did their

the children know that this is something they share, they can't keep it, they show how they relate to people in society, they are a part of a historical narrative, and engaged in processes of becoming where the artistic messages "The medium is the message, so to speak", which goes in line with what Arendt (1998) and Dufrenne (1973) stress, that art works survive humans. The colleagues have also suggested that formal ways as "error reports", where broken lights, or fallen trees, for example should be reported, could be used to reach the politicians, which is in line with what Arendt's thinking of pluralism in politics, also protests towards. Even if security during the transportation to, as well as in schools, is something that is important according to the Children's rights convention, to use such established channels, is another view of democracy, that is not connected to becoming of "who's" nor deepened understanding offered in relation to art.

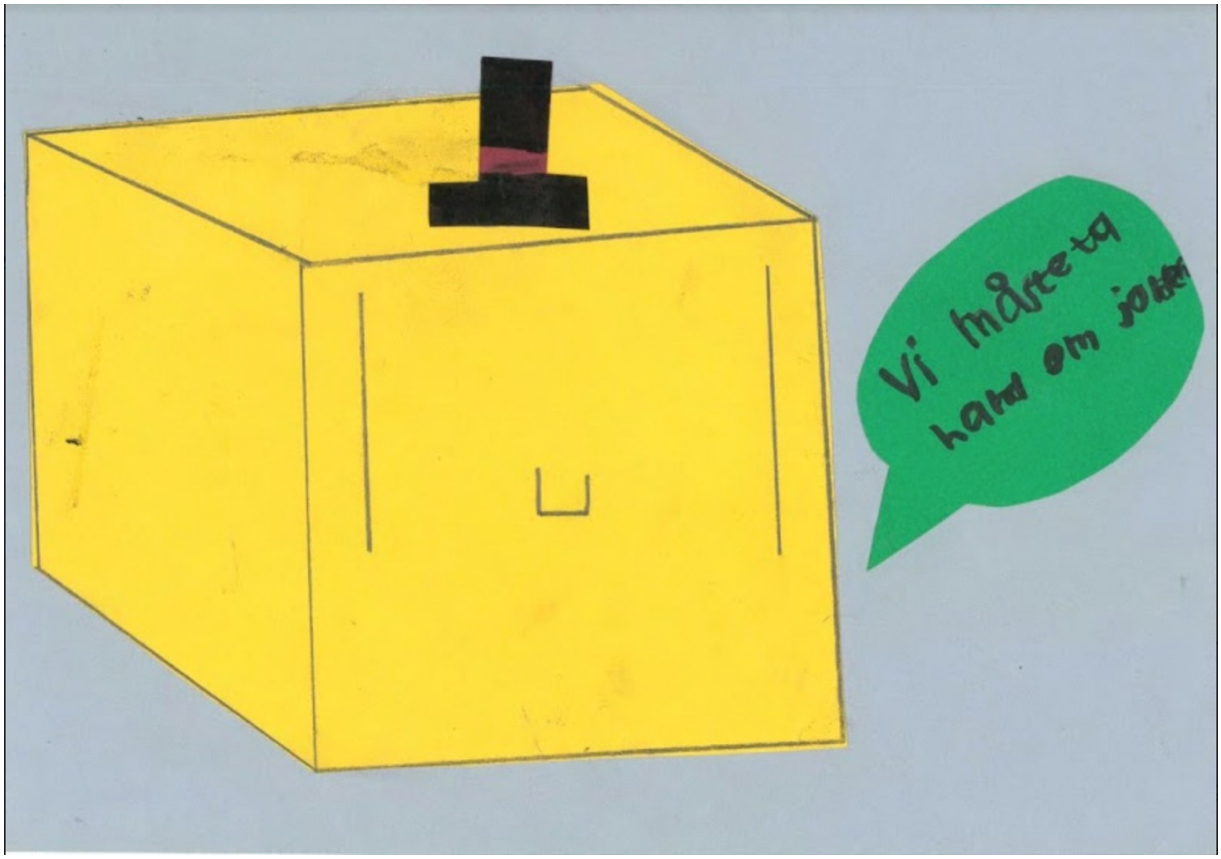

Figure 4. *We must take care of the earth.*

There are also several messages and questions in the material formulated by the children that are not developed in postcard artistic processes, but are partly mediated through a common avatar, who speaks digitally to the politicians. "So that politicians can go there and check out what the avatar says right now". The original intention was that the avatar should speak at council meetings, but *Kulturverket* couldn't imagine how that could be possible to realize. In these gathered messages the children are more open, and "uses" the freedom of speech. In the post-

and an imagined politician, a process of becoming a "who" in plurality. But even the politicians must be "hit" to come up with a reaction, and answer "In the newspaper or at their meetings or something". Otherwise, the children will just be heard, and not listened to, and then the democratic intention has failed, and the project can't be defined as sustainable.

The children went by bus to the municipal house city hall to be present when the postcards were given to the politicians. "Like a mini-demonstration". They were making their voices heard, they were taken seriously by *Kulturverket*, but were they listened to by the politicians? The chair of the cultural committee had been contacted and received the postcards in person. There is a hope that the post cards are shared among the politicians, that they can put them on the walls in their offices or be exposed in an open space at the city hall, to continue displaying the children's voices (Dufrenne, 1973; Arendt, 1998). "Because these are originals. I am so afraid that something will happen to them".

Figure 7. *The children and the avatar give the postcards to the politician.*

The poet-pedagogue had thought about letting the politicians participate in a similar post-card workshop as a way of answering the children, but he couldn't imagine who potentially could receive their mail. In line with Arendt's (1998) thinking, the children should be the natural receivers – a chance to not just be heard, but also listened to. Now of writing this paper, an interview with one politician is planned to be conducted and recorded, and then played in public at a public exhibition.

In addition, the gathered messages are mediated through artistic treatment on another level, namely through the poet's own artistic poetic work. "They wright so beautiful sentences now and then. It gives me so much". The messages live further on through the relay-model, in a poetry book, also present at the public exhibition. The children will hopefully get the feeling of being a part of something bigger. There will also be a speaker's corner including poetry reading, based on the children's voices.

Figure 5 *More breaks. Children need to rest.*

As mentioned, the messages are shared and mixed through a common Avatar, A 3D-animated figure on a webpage. The intention is to influence politicians, to be touched and engaged, through the sensuous (Dufrenne, 1973), a prerequisite for the children's voices to be listened to, "But how is that done, it's a really hard question"? Even counter arguments are signs of touch and engagement, and that the children are listened to, an important aspect of their process of becoming

if a child-avatar appeared and posed their questions. So far, the avatar is available, and share the messages of the children at a web page. https://kulturverketumea.se/dkv/builds/digitalavatar/.

An application is also constructed, which makes it possible to continually gather and share children's artistically identified, treated, and expressed thoughts, visions, and desires. But still, what about the politicians' reactions?

Figure 6 *I want answer. Why did you close the school at Brännland?*

The mentioned public happening, the exhibition, is about to be organized for the whole project, where the plan is that one important politician will come and speak (back) to the children, which is a part of the story to be continued. But it can be stated that such a response would be crucial in the common place that the public exhibition constitutes, a political space, where human beings – in this case politicians and children – meet to try out, sharpening and equal views and standpoints, at the same time as they create the specific square, if we listen to Arendt (1978).

4. Conclusions

The results show how processes of identifying, treating, and expressing ideas in interplay with art can be performed, and how such educational situations demands imagination, collaboration, flexibility, openness, and courage. The participating children's thoughts and artistic expressions

the results can't fully disclose how the children's ideas were met by the local politicians, or if their ideas will be acted upon. Aspan & Balldin (2017), in line with the thoughts of Arendt, underlines the fact that children must not only be given opportunities to express themselves, but also be listened to, and experience that their ideas are acted upon. To make children's voices heard and listened to by politicians in and through arts constitute one possible, but demanding, thread in a sustainable social network beyond the Anthropocene – towards "social sustainable development and courage, culture, art, and human rights".

The Children's rights convention is regulated by law in Sweden since 2020 (SOU 2016), and Swedish school curricula are based on democratic principles (Skolverket, 2022). Also, the Swedish government describes that a sustainable society as well as ESD should be based on democratic principles and a holistic view on human and societal needs (SOU, 2004). In line with Aspan & Balldin (2017) and Illeris (2017), the result also shows how knowledge production is seen as co-created and holistic. Earlier research underlines that ESD should strive for knowledge production and agency towards societal transformation, focussing on sustainable development for learners in all ages (SOU, 2004). This can be seen as an incentive for running similar projects like *Alla har rätt* in schools – projects where children's artistic expressions of views on issues that relate to them reach others and create a space for reflection and possibly grounds for action, in line with Dahlbäck & Schmidts (2021) recommendations. But, again, in the planning and running of such processes, the aspect of being listened to and acted upon, must be considered.

As stated in earlier research, taking children's ideas as a starting point for societal change can be seen as challenging Anthropocene by taking children seriously and address issues that concern them (such as ecological, cultural, and social human relationships in the world) (Fedosejeva et al., 2018; Furu et al. 2021). In a recently performed research study, we found that another of *Kulturverkets* projects – Sammankonst – worked contradictory to neo-liberal powers established in the Anthropocentric world (Ferm Almqvist & Hentschel, in press). We underline the importance by acknowledging that changing practice lies greatly in the hands of leaders, like in this case, politicians. If children's voices (through artistic expressions) are only heard but not listened to and acted on, practices can't be changed (Quinn, 2010). As Arendt (1978) claims, children's "who´s" are intertwined with nature, society and historical narratives through creative action, and their expressions are to be treated as a crucial part of their citizenship. To bring forth change, organizational, collegial, and political areas need to reinforce holistic views on knowledge and competence in contradiction to Anthropocentric values (Ferm Almqvist & Hentschel, in press), where children's "who´s" expressed through art is taken as serious participants in the debate on how to go beyond the Anthropocene and act. To promote sustainable participation in actual change of societal practice, we need to treat children as equal discussion

Legal and Institutional Framework on Forest Confronted with Colonial Hrauma: how to decolonize and achieve SDG 15 in DRC?

PhD Candidate ROGER Mbuyu Kimpesa Kasulo

University of Kinshasa, Kinshasa, Congo, the Democratic Republic of the

Abstract

The Democratic Republic of Congo (DRC) is a vast country whose forests are central to the preservation of ecosystems services, biodiversity, climate and the planet.

During the colonial era, since the formation of the Congo Free State, these forests have largely been logged for the benefit of the Belgian King Leopold II, the Belgian State and other foreign European companies to the detriment of the Congolese State, including its people and institutions. Forests communities paid a horrible heavy price in terms of forced labour, denial of all human dignity, desecration of forests, despoiling of vital resources and habitat. Rubber extraction cost millions of human lives considered as the first genocide in DRC, while logging destroyed their habitat. Plantations production and the establishing of protected led local communities to work under ruthless conditions or to be expelled from their lands with negative cultural and well-being impacts.

As a result, these worse unequal experiences rooted traumas in the DRC's population and generate a distrust of the ancient colonial government (Western Countries), the logging companies and the State considered as a collaborator of the precedents.

After independence in 1960, the DRC maintained the enforcement of a 1949 Decree on the Forest Regime 42 years later and adopted, since 20 years, the 2002 Forest Code. The 1949 Decree disregards the ownership of forests by the population and sets conditions for logging that were out of reach of the population. The 2002 Code has brought innovations without completely decolonize the forest management system.

Investigating on the survival colonial model in the current legal and institutional framework and the state of forest projects in DRC will contribute to the understanding on the participation of the populations to domestic and international initiative on forest conservation measures, such as the REDD+ and the Agenda 2030.

The paper focuses on the implementation of the SDG 15 on life on land and proposes the decolonization of the legal and institutional framework on forest to foster the participation of the population by alleviating colonial trauma and promoting good practices in line with the Agenda 2030. Cultural, historical and well-being aspects should be the centrepiece of the implementation of the SDG 15. The paper highlights the courage of actors of change who contribute to shift the paradigm on forest protection and promotes the participation of the populations to the optimal enforcement of SDG 15.

Enhancing Sustainable Development on Land: Using birds of prey to disperse flocks of native birds that threaten resource use and human activities

Robert Wallis[1], Graeme Coles[2]

[1]*Federation University Australia, r.wallis@federation.edu.au*

[2]*Full Flight Birds of Prey, graeme@fullflight.com.au*

Abstract

One of the aims of SD Goal 15 *Life on Land* is the sustainable use of terrestrial ecosystems. When development of infrastructure, agriculture or other human use of the land is threatened by fauna that congregates in high numbers to exploit the resource under development, this sustainable use is in turn threatened.

Large flocks of birds at times can be particularly troublesome. Traditional control techniques have included poisoning, trapping and relocation, exclusion, use of decoys and loud noises and habitat manipulation such as provision of alternative food sources away from the target site. These methods have disadvantages, often including low effectiveness in actually dispersing the target birds.

We have used birds of prey (raptors) to successfully disperse flocks of pest birds that have threatened agricultural harvests, damaged sporting fields and infrastructure and posed high nuisance value at sporting events. The technique works best when the birds' damaging activity is localized and over a short time period. As it involves trained birds and skilled bird handlers, the technique is expensive but is cost-effective if the potential damage is significant and expensive.

The management of large flocks of pest birds that are native (as opposed to introduced) adds another challenge. The public can be less forgiving of the need to destroy the pest birds if they are indigenous to the area. Using raptors (birds of prey) to disperse – as opposed to kill the birds that cause damage - is an example of compassionate conservation where animal welfare (no harm) is of concern.

Here we describe case studies in Australia where the use of raptors has been effective in managing flocks of pest, native birds and one example in which the technique was less effective. The raptors have included eagles, owls, goshawks and falcons used to manage cockatoos and gulls. We also describe how we use the raptors for the control trials.

By carefully managing large numbers of native birds that threaten agricultural production or human community activities, the sustainable use of the land might be better achieved without loss of biodiversity.

Keywords: pest birds, control, raptors, Australia

1. Introduction

The sustainable development of terrestrial ecosystems is central to SD Goal 15 *Life on Land.* This goal involves the wise use of forests, preventing desertification and halting the loss of biodiversity. These

forest growth as well as contribute to desertification and biodiversity loss. The birds can also disrupt community activities and damage infrastructure.

Large flocks of birds – both indigenous and introduced to the area, can seriously disrupt ecosystem function and threaten the sustainable use of terrestrial resources. In agriculture, they can consume fruit and grain, foul the harvest, introduce disease, prey on other birds that consume insect pests and destroy the structural integrity of the crop (Garcia et al., 2020). Pest flocks can also lead to loss of local biodiversity, either through direct consumption or competition. Isbell *et al.* (2017) have demonstrated the link between loss of biodiversity and changes in the delivery of ecosystem services. Pest birds can also damage buildings, recreation facilities and disrupt community events (Coles et al., 2019).

Traditional methods of managing bird pests have included poisoning, trapping and relocation, exclusion, chemical repellents, habitat modification and using various scaring devices (Rivadeneira et al., 2018). Each method has disadvantages and these authors have argued that a multi-tiered, integrated pest management approach is likely to be the most effective in the long-term.

In this paper we discuss the use of birds of prey to disperse pest bird flocks in Australia. Using case studies, we evaluate the pros and cons of this technique and consider whether lethal (as opposed to non-lethal) takes by raptors might be more effective at managing bird pests. Our case studies include bird problems in agriculture, at sporting events and those that damage infrastructure.

2. Use of birds of prey to manage pest birds

Falconry has long been a recreational pursuit, but it has also been recognized for its value as a pest bird management tool. If we expand the technique to include other birds of prey (raptors), then there have been several studies on the effectiveness of bird hazing as a means to disperse pest bird flocks.

The earliest accounts of raptors dispersing pest birds were in managing airfields. Indeed, a conference held in Nice (France) in 1963 was specifically devoted to birds interfering with planes flying into bird flocks (especially gulls) (Busnel and Giban, 1965). Blokpoel (1976) reviewed the use of raptors that had been trained to scare birds at airports in five countries. His conclusions were quite specific: the technique did work effectively but required trained birds of prey, skilled handlers and
the technique's efficacy depended on the species of pest bird. Furthermore, the technique required daily flights by the raptors and only worked in good weather and during daylight hours. He also concluded the technique was quite costly and if every airport used raptors, then there would be insufficient trained ones in the world to manage the pest birds! Other studies successfully used raptors in combination with other bird-frightening methods such as shotgun patrols, taped distress calls and visual deterrents (Heighway, 1969; Mikx, 1969; Boulay, 1977). However, because other techniques were used, it is difficult to ascribe the success at managing the pest birds to these or the raptor hazing.

Another early study compared the effectiveness of using goshawks (*Accipiter gentilis*) to manage woodpigeons (*Columba palumbus*) on brassica crops. The technique failed, perhaps because of lack of

There have since been numerous reports of the successful use of raptors to manage pest birds in agriculture. These include falcons (*Falco* spp.) dispersing several species of birds that consumed leafy greens in the US (Navarro-Gonzales and Jay-Russell, 2016), falcons controlling introduced and a native species of birds that attacked grapes in New Zealand (Kross et al*.,* 2012), magpies (*Cracticus tibicen*) disrupting frugivorous birds that damage grapes in Australia (Peisley et al*.,* 2017), models of sparrowhawks (*A. nisus*) disrupting starlings (*Sturnus vulgaris*) feeding on rye grass in the UK (Devereaux et al*.,* 2006), and American kestrels (*F. sparverius*) dispersing birds that consumed cherries in Michigan, US (Shave et al*.,* 2018).

Raptors have also been used to control scavenging birds at rubbish dumps (landfill sites) with varying levels of success (Baxter and Allan, 2006; Cook et al*.*, 2008; Soldatini et al*.,* 2007). Success again depends on the species being controlled, the length of the period over which raptors are flown and whether other techniques are employed simultaneously.

3. Lethal versus non-lethal conditions

Using birds of prey to disperse pest birds without killing those target birds is considered a humane method of reducing the deleterious impacts of the pest population – certainly when compared with such methods as poisoning, shooting and trapping and translocation (Blokpoel, 1976).

If the raptor kills (or hunts and therefore has the potential to kill) some of the target population, does this increase the efficacy of the control method? There have been few comparisons between lethal and non-lethal use of raptors that allow for meaningful comparison. Baxter and Allan (2006) found peregrine falcons (*F. peregrinus*) significantly reduced the number of gulls at rubbish tips in England. In about one third of their trials, the falcons were able to hunt and capture their prey.

However, their data analysis did not discriminate between the prey reduction for lethal versus non- lethal trials. The authors surmised the falcons were successful "whether hunting, being flown to simulate hunting. Or more importantly, perceived as potentially present" in deterring the gulls from using the tips (Baxter and Allan, 2006 p. 1165). However, the experimental design did not allow any conclusion to be drawn on the relative reduction in gull numbers for three conditions: falcons that did not hunt, simulated hunting and falcons that actually took prey.

In another study of landfill rubbish tips in the UK, Cook et al. (2008) found that when lethal methods were used (falcons preying on gulls or the gulls being shot), the gulls no longer habituated to the raptors (which occurred when the birds did not hunt their prey). They found lethal techniques (shooting, falconry) which reinforce visual and audio cues with the occasional death of target birds, have the opposite effect on habituation and more gulls were deterred as the trial progressed. This is the most striking evidence that lethal takes (and shooting) do indeed have a positive effect on reducing numbers of gulls compared with non-lethal use of raptors.

In a study on grape damage in New Zealand previously mentioned, Kross et al. (2011) found New Zealand falcons translocated to wine-growing regions preyed on birds that fed on and damaged grapes. The

predation risk changed the birds' behaviour to become more "antipredator". Such actions included avoiding the sites, increased vigilance relative to the time spent actually foraging for grapes and also relocation by the frugivorous birds to less favourable sites in which to forage that had a lower predation risk.

There seems to be other anecdotal suggestions that if raptors can kill their prey, the control of pest flocks becomes easier, but hard evidence is lacking. In some cases, it seems authors intuitively think this should be the case without any experimental evidence. Thus Erickson et al. (1990, p. 314) state "The raptor species used preferably should be a natural predator of the pest bird species as the occasional kills it makes will help reinforce the perception of danger" and cite Grubb (1977) in support. However, Grubb (1977) makes no mention of lethal versus non-lethal control using raptors, referring to differential habituation only in terms of distinguishing between different aerial stimuli such as different shapes of raptors.

Inglis (1980) also believes shooting pest birds and the sight of dead or dying birds are aversive stimuli that could disperse pest birds from a site. His argument is based on the literature of avoidance conditioning. However, there are certain elements in its practice that are required:

The warning stimulus (in this case, birds seeing others taken by a raptor) must retain its potency for long periods (a single kill episode will likely be ineffective)

- It must occur spatially and temporally with the pest bird visits to the site (obviously!)
- A scaring device (such as the playing of alarm calls) could be used simultaneously with the aversion stimulus (e.g. hazing by falcons) so the pest birds associate the device stimulus with killing
- Novel scarers are preferable to ones used previously.

Inglis' suggestions are based on theory and his paper does not produce hard evidence that killing some of the pest birds as aversion stimuli actually increases the efficacy of pest dispersal. Furthermore, in his discussion the aversion stimulus of dead conspecifics is by way of shooting and not by raptor take.

Bomford and Sinclair (2002) reviewed the research on bird pests in Australia and listed the circumstances when scaring devices could be effective, including their reinforcement with real danger, such as shooting. Raptor takes of target birds could also be considered such a reinforcement stimulus.

Clearly there needs to be research undertaken that resolves whether lethal takes of pest birds reduce the impact they cause.

Lethal takes by raptors are likely to distress some in the community. Witnessing a predatory bird seize and consume a prey can be off-putting (Bird-control, 2022; Pigeon control resource centre, undated) and therefore likely to prove unpopular with the general public. This needs to be weighed against any increase in efficacy in dispersing the birds and the resultant reduction in damage and economic loss.

4. Methods and Results

In Australia we have successfully used birds of prey to disperse flocks of pest birds (Coles *et al*, 2019;

to infrastructure and (c) interference with sporting events.

2a. In the first case study we studied cockatoos that have threatened the harvest of almonds in a large orchard in northern Victoria.

The Olam Group is a large, multinational company based in Singapore that owns and operates almond farms in northern Victoria, some 120 km east of Mildura (Fig. 1). The total area of the farms is quite large – 12,000 ha and comprise 11 separate orchards – the largest of which has 320,000 almond trees. Flocks of Long-billed Corellas *Cacatua tenuirostris* and smaller numbers of Sulphur- crested Cockatoos *C. galerita* (both species hereinafter referred to as 'cockatoos') cause damage to the crop. These parrots roost overnight in trees along the nearby River Murray and fly to feed on the almonds during the day. The highest densities of parrots occur on the farms in the mornings.

About 400 parrots would fly from the river each morning and late afternoon along certain transit routes to the orchards. In the 2017 trials we used a trained Wedge-tailed Eagle (*Aquila audax*) to fly from the river to three adjoining farms along these transit routes. Three periods of flyovers, each lasting six days were conducted during the pre-harvest period. Flyovers consisted of the one handler releasing the eagle and another handler receiving the eagle that flew over a distance of about 200 metres at a height of 3-5 metres during early morning and late afternoon when the parrots were most actively flying to the almond trees. This was repeated during late morning when some parrots would attempt to return to the orchard. The eagle was attracted to the receiving handler rotating a lure; when the eagle landed on the handler's gloved hand, it was rewarded with food. The eagle had been trained not to attack or pursue the cockatoos but simply fly over in a direct line.

The parrots quickly returned to the river habitat after each flyover rather than dispersing further inland to the other farm blocks. As the trial progressed, fewer parrots would attempt to access the orchards. After the 18 days of flyovers, the parrots did not return to farm blocks until several months later when harvesting had finished.

In 2018 we repeated the trial. Again, about 400 parrots attempted to fly to the orchard each day, especially in the early morning and late afternoon. This time, low numbers (<10) of cockatoos returned during the day. We thus checked the farms every 30 minutes during the six-day period and flew the eagle an additional time if parrots were seen in the almond trees. This was effective and after the six days, no parrots were foraging in the orchards.

Importantly, we observed opportunistically that smaller, non-target birds did not respond to the eagle flying overhead.

2b. This case study involved a number of sites where cockatoos damage buildings, playing fields and golf course.

Native cockatoos (mainly corellas) cause significant damage to golf courses which provide the birds with bulbs, seeds and grasses as food. The birds tear up rhizomes and tubers as well and not only does the

Parliamentary Committee recommended management by shooting corellas (suggesting shooters disguise themselves as golfers and carry rifles in their golf bags!) and sounding alarm calls (Environment and Natural Resources Committee 1995).

We have worked on many golf courses in Victoria, Australia; their large area means birds can often be dispersed from one section of the course and relocate and damage another part. However, over time we have increased the success rate in damage mitigation and cockatoo management. One case study will be described here.

In April 2018 we flew either a Wedge-tailed Eagle or a Brown Goshawk (*Accipiter fasciatus*) over a golf course in Melbourne's south-east to disperse Little Corellas *Cacatua sanguinea* that were causing damage to the course putting greens. The corellas were especially abundant around a small dam on the course. If no corellas were observed on the greens near the dam, then the raptor was not flown. Checks were made up to six times a day for five consecutive days. A maximum of 50 corellas was observed at any one time. In all cases, they dispersed when the raptor was flown. In the early stages of the treatment, corellas returned in lower numbers within one hour. However, as the week progressed, corellas returned less frequently until by day five, no corellas were observed at all on the course.

Corellas remained absent from the course for eight months after the treatment but did return in small numbers after this. Repeated use of the eagle then quickly dispersed the corellas. An advantage of this study site was the corellas roosted in trees by a particular dam and did not disperse to other parts of the course after the bird of prey had been flown.

Little Corellas were also causing damage to the trees and sporting fields of a school in south-eastern Melbourne in 2018. Flocks of up to 400 corellas were observed. Three raptors (Wedge-tailed Eagle, Brown Goshawk and Masked Owl *Tyto novaehollandiae*) were flown daily for four days in July until corellas no longer appeared at the site. Two weeks later a large flock of corellas again returned to the school. This time the eagle was held on the hand and encouraged to flap its wings. On hearing the flapping noise, the birds dispersed. After two days, no corellas were seen and had not returned by the end of the year. This case study enabled us to test the efficacy used three raptor species as well as comparing the effects of flying the birds over the target species versus holding the eagle in the hand and having it flap its wings. The results of this latter set of trials need further analysis and more data collected before we can make definitive conclusions about the effectiveness of each operation.

Long-billed Corellas can cause damage to buildings (Environment and Natural Resources Committee 1995). In 2016 a flock of about 300 corellas were damaging an apartment block in Caroline Springs, an outer suburb in Melbourne's north-west. They were chewing wires, rubber seals and window seals, defaecating on the buildings and its grounds and their screeching was annoying guests. Our treatment to disperse these birds involved using one Barking Owl *Ninox connivens* and one Wedge- tailed Eagle over three consecutive mornings at the site. We used three techniques: flyovers by the raptors, encouraging the raptors to flap their wings or holding the birds still in the hand. Flying the raptor over the site proved the

eagle flap its wings to disperse the birds. After two months no corellas had returned to the site.

At another apartment block in Frankston, an outer south-eastern suburb of Melbourne, roosting Silver Gulls *Chroicocephalus novaehollandiae* on the roof of an apartment block could not be dispersed by flying raptors over the building. The gulls were nesting on the roof and were fiercely protective of their young, readily mobbing the raptors that were used.

2c. The third case study involves pest birds interfering with sporting events.

In 2015 at a Melbourne racecourse, a flock of Silver Gulls flew up in front of a group of thoroughbreds racing, spooking the horses and causing falls of horses and jockeys. Fortunately, no horses were put down, but jockeys were hospitalised and the race abandoned. To prevent a recurrence of such an event, the Victoria Racing Club has engaged Full Flight Birds of Prey every year since 2015 to disperse gulls during the prestigious Melbourne Cup Carnival which is considered the premier set of racing events in Australia. The gulls are attracted to where the crowd of over 100,000 congregate, perhaps attracted to the food dropped by the patrons. The Carnival runs over four non- consecutive days and involves 37 races.

We have used the opportunity to use different raptors as well as measuring numbers of gulls on the track 5 to 10 minutes before each race and during the race itself. We did not count numbers of gulls besides the racetrack (in the public area or in the space enclosed by the elliptical track) but on most occasions hundreds were seen in the marquee areas or flying overhead.

One bird of prey was flown over about half of the course (where the gulls congregated) immediately before each race. The raptors used over the years have been Peregrine Falcon (*Falco peregrinus*), Wedge-tailed Eagle, Barking Owl, Masked Owl, Barn Owl (*T. alba*) and Brown Goshawk. The birds were released by a handler near the start of the race and trained to fly to another handler at the end of the trial distance of approximately 1000 to 1400m. The number of gulls at the course has varied over the years but around 200 to 400 can flock in the middle of the course (off the track) during the events. Many land on the course between races; for example, in 2021 about 200 gulls were found on the actual track before the start of two races, including the Melbourne Cup race itself.

The dispersal of the gulls has been successful with no gulls ever found on the racetrack during the 37 races after the flyovers in each of the years before 2021. Furthermore, when a raptor flew overhead, gulls in the public areas off the track also took flight and dispersed for a short time, but never on to the track. In 2021, however, for the first time we observed gulls resettling on the racetrack once the race had begun. Numbers were very low on the few occasions this occurred e.g. three gulls flew across the horses as they ran to the finish line on Race 4, Oaks Day. In the 2021 trials, we also flew birds repeatedly before certain races to ensure gulls flew away from the track. Thus, before race 7 on Melbourne Cup Day, the owl was flown six times before the race. This was the Melbourne Cup Race itself and we wanted to be certain no gulls could congregate. Before race 8 on Oaks Day, the eagle was flown 10 times.

All species of raptors were effective in dispersing the gulls from the track, although there were insufficient

disruption to the horse races due to gulls. No injury or deaths of the raptors or gulls was observed during the trials and gulls were not seeing harassing the raptors.

5. Discussion

The recent COVID 19 pandemic has reduced the opportunity and our preference for further trials of dispersing pest birds in agricultural settings. The success of the eagle in mitigating the loss of almonds during harvest illustrates advantages this technique offers in pest management. These advantages include:

- no poisoning and deleterious effects on non-target species
- the technique uses a natural predator of the pest birds and has little impact on the animal welfare of both raptor and target and non-target birds
- low habituation of the target population to the raptors (compared with use of birds of prey models, loud noises, flashing lights etc.)
- compliance with Olam Group's sustainability commitment (Olam Group, 2019).

A further advantage in using the eagle to manage the cockatoos is that some time after the eagle has been flown, the cockatoos will return and clean up the rotting fruit left unharvested on the trees and ground (Saunders et al., 2016). If the cockatoos had been removed permanently by shooting, trapping or poisoning, the fruit that had been left would need cleaning up using other, costly methods.

The method also exemplifies compassionate ("no harm") conservation (Wallach et al., 2018) which reflects growing concerns of the community for the welfare of wildlife that is being managed, although some have argued compassionate conservation can actually work against effective conservation outcomes (Rower & Maris, 2019; Callen et al., 2020).

The case studies also demonstrate the technique is effective in dispersing cockatoos from urban sites where they are damaging buildings and infrastructure, although not nesting Silver Gulls that mobbed and harassed the raptors. Soldatini et al. (2007) described gulls of the genus *Larus* as highly social and intuitive bird species when testing the efficacy of three systems used to deter gulls from scavenging at refuse dumps in Italy. Silver Gulls have also proved difficult to disperse at Sydney airport using peregrine Falcons (Olsen 1994).

6. Conclusion

SD goal 15 promotes the sustainable use of terrestrial ecosystems to ensure no loss of biodiversity and sustained availability of resources for future generations. These aims can be compromised by human activities that encourage large flocks of native birds that damage agricultural production efforts, damage infrastructure and interfere with community activities. Traditional methods of control of pest bird aggregations such as poisoning, shooting, relocation and exclusion can deleteriously affect the sustainable development of human communities, the sustainable use of terrestrial resources and may have animal welfare consequences that are unpopular.

technique exemplifies 'compassionate conservation' in that there is no harm to both the raptor and the target birds.

The technique has worked well when the pest birds cause damage in a localized area over a specific time. Our trials are continuing to determine which raptors work best with particular pest species, and whether flying the raptor over the flocks of birds works better than using a tethered raptor and allowed to fly upwards or one that is simply hand-held. We also would like to use this technique of dispersing pest birds using raptors in conjunction with other methods, such as providing alternative food sources or habitat for the target populations. It will also be interesting to see whether the authorities will permit us to allow the birds of prey to hunt some of the prey that are causing the damage to test if a lethal take increases the techniques' efficacy. More work also needs to be undertaken on whether the effects of raptors on resident birds is the same as for migratory or transient flocks.

Using raptors is expensive – it requires trained and qualified bird handlers and usually several birds of prey on each trial. The technique is less effective for some target species in some circumstances (e.g. breeding gulls) and where there are several sites to which the birds can relocate and then re- invade once the raptors have ceased their flyovers.

Landscape-based Strategies to Avert Human-Elephant Conflict

A perspective from Assam's tea plantation regions

Barsha Amarendra[1], Prof. Amarendra Kumar Das[2]

[1]*Indian Institute of Technology Guwahati, b.amarendra@iitg.ac.in*

Abstract

Ever since the beginning of imperial tea and coffee plantations in India, elephants have assumed a quintessential role within the framework of plantation establishment and development. Within the British Tea Estates, elephants were revered, tamed beasts. This reverence, however, soon turned sour upon encountering their wild counterparts, who wandered in herds and trampled through plantations and habitations. Years of systematic habitat destruction and fragmentation under the pretext of plantation expansion and settlement growth have rendered the wild elephants restricted in their area of movement and food sources. Owing to the human-curated circumstances of habitat loss and starvation, wild elephants are compelled to roam closer to human habitations, sparking conflicts. Affected humans poison or electrocute them or blow them up by placing crude bombs in delicacies like jackfruit. Heightened conflict in the plantation regions and the fact that elephants are an endangered species has become a bone of contention for plantation owners. While many owners are split over a sustainable solution, few have attempted to employ sustainable landscape design solutions to harbour a peaceful coexistence. The paper seeks to highlight the variety of landscape design strategies incorporated into Assam's tea plantations for negating human-elephant conflict. The paper employs fieldwork to document the strategies devised by different plantation regions, supplemented by interviews with concerned stakeholders. The paper creates a comprehensive, visual toolbox of existing design strategies that interested stakeholders can implement. By doing so, the paper initiates the discussion towards cataloguing landscape-based solutions for preventing human-elephant conflicts and situating these solutions in a comprehensible, visual style that can guide various stakeholders concerned.

Keywords: Asian Elephants, Assam Tea Plantations, Tea Plantation Ecology, Habitat Enrichment, Sustainable wildlife co-existence

1. Introduction

The narrative of the intertwined lives of Asia's largest land mammal and the humans of the Indian subcontinent dates as far back as the 4th Century BCE. Formidable in their physique and regal in their aura, the Asian elephants were upheld as a valuable royal asset amongst the great dynasties that wielded control over the sub-continent. Elephants were deemed the suited carrier for the kings and an

indispensable part of a kingdom's warfare. The benefit lay not only in their sheer size but also in their concern for their human trainers (Ramaswamy, 2016). For the kingdom's common folk, elephants were sacred beasts. In Hinduism, elephants were regarded as a personification of Lord Ganesha, the elephant-headed god of beginnings. In Buddhism, elephants were considered holy guardians from whom Lord Buddha eventually reincarnated into a human form. As a result of these attributes, elephants in the country were treated with great reverence by the entire Indian populace. This veneration for the elephants extended even into the years of the British Raj. The British administration in India continued the local ruler's traditions of employing the elephant's resourcefulness in military conveyance. They humanised their association with the elephants by naming and mustering them (Sivasundaram, 2005). Similarly, elephants continued to be regarded as an advantageous locomotive asset under the British Raj. Their role in the European colonisation through logging and transportation involved in building roads, railways, and other infrastructure projects cannot be overstated (Ramaswamy, 2016). They were also used to traverse the country's difficult terrain. Additionally, the British recognised elephants as good hunting friends (Singh, 2020). This British appraisal of the elephant's human-like qualities greatly influenced the beginning of the wildlife protection policy in India with the Elephant Preservation Policy of 1879 (Singh, 2020).

Despite all this endearment, the British Enterprise in India, particularly Assam, has been detrimentally involved in the Asian elephant's present-day existential crisis. The discovery of tea in Assam prompted the legislation of Wasteland Grants that allowed vast tracts of forestlands and grasslands in the state to be cleared for tea plantations. In 1839, a year after the First Wasteland Grants came into effect, 2,638 acres of tea plantations were established amidst Assam's wilderness. By 1873, following two amendments in the Wasteland Grants, the area under tea plantation expanded to 2,35,852 acres (Projapati, 1984). This expansion in acreage continued at a swift pace well into the 1920s, after which it slowed down considerably till 1993. Starting in 1993, the state witnessed an unprecedented mushrooming of new tea plantations due to the state Government's encouragement of small tea growers. Consequently, by 2011, the total area under tea cultivation in Assam increased to 322.21 thousand hectares, at considerable cost to wildlife habitats. This situation is more distressing because British planters employed elephants to tear down their own habitats for conversion into tea plantations. Figure 1 depicts the imagery of elephants clearing the forested grounds for tea cultivation. The parallel trajectories of large-scale agricultural expansions, the unchecked and unplanned proliferation of human settlements, and callous infrastructural development further aggravated this situation of habitat loss. It culminated in Assam's resident population of 5,719 wild elephants presently confined to the state's largely fragmented reserve forests, 22% of the elephant's forest habitat being encroached upon (Bhattacharya, 2019). Only a mere 12.9 per cent of elephant corridors connecting the fragmented habitats are under forest cover, while the rest are in mosaics of different land use, such as human settlements, agriculture or tea gardens (Sharma et al., 2022). Additionally, unregulated human extraction of forest produce from these limited forest fragments has degraded elephant habitats' quality and significantly reduced forage availability (Sharma et al., 2022).

Figure 1. *Elephants are clearing their habitats for tea cultivation to commence in Assam.*

Subjected to these circumstances, elephants have been forced to change their migratory routes and stray toward human settlements in search of food, thus bringing the animals into more frequent confrontations with humans (Amarendra & Bhuyan, 2022). Often, these confrontations result in deadly outcomes. Between 2010 and 2020, the Assam Forest Department recorded the death of 825 elephants due to the human-elephant conflict; many of these were reported from the state's tea plantations. This occurrence arises from the combination of two factors. Firstly, most tea plantations are located adjacent to forest fragments, making their resident community vulnerable to elephant encounters. Coupled with the community's practice of cultivating paddy once a year, the elephants get drawn into the territory of the tea plantations by the fragrance of the paddy fields. Secondly, elephants perceive tea gardens as extensions of their forest habitat, as they have been part of their migratory routes over centuries (Sunder, 2020). The relatively higher canopy cover found in the tea plantations is a preferred resting point for elephants during the day while migrating between foraging grounds. Sometimes they use plantations as a 'base' to forage on succulent crops in outlying areas (Bhattacharya, 2019). Figure 2 shows elephants using the tea plantation's canopy-covered areas as resting points during the day.

Figure 2. *Elephants perceive tea gardens as an extension of their natural habitats.*

Although this intricate positioning of the tea plantations in the elephant's constrained existence results in numerous fatalities each year, it also presents a unique opportunity to protect the state's wild elephants. In recent years, the conversation around elephant-friendly approaches for conflict mitigation has motivated plantation owners to explore landscape-based conflict mitigation solutions. This paper analyses the landscape-based solutions implemented in the tea plantations for ensuing a peaceful co-existence against the broader backdrop of the varied strategies presently employed to mitigate human-elephant conflict. In doing so, the paper brings forth a comprehensive understanding of the Asian elephant's essential necessities and how they can be satisfied by enriching the elephant's preferred stepping stones, in this case,

landscape-based conflict mitigation solutions have been highly muted. The present paper bears significance for its attempts to initiate a dialogue on the new paradigms of elephant protection.

2. Methods

The sensitivity surrounding the discussion of human-elephant conflicts in Assam required formulating a methodology to gather data through different qualitative methods for the enquiry to result in a well-founded narrative. The methodology developed for the paper comprises four phases. In the first phase, newspaper clippings on the human-elephant conflict in Assam were gathered from 2010 to 2022. The newspaper clippings so compiled were categorised under the tags of elephant casualty, anti-elephant strategies and elephant-friendly strategies. The significant proportion of clippings concerning elephant casualty necessitated an understanding of the reasons for the advent, persistence and heightening of human-elephant conflict in Assam. The second phase, thus, reviewed opinion pieces and interviews in newspapers, along with books authored by native scholars, conservationists and activists, to discover this pretext. In the third phase, the clippings tagged under anti-elephant strategies were evaluated for their commonality of use and frequency of being the reason for elephant casualty. These strategies were then cross-examined against government directives and reports to understand the causes for the continued perpetuation of such trends. The fourth phase comprised an analysis of the last clippings, those tagged under elephant-friendly strategies. Strategies that exhibited a landscape-based approach were filtered out, and the implementing tea garden management was contacted to conduct field visits. The field visits were programmed to witness the strategies being implemented first-hand while also partaking in unstructured walk-along interviews to ascertain the effect that these solutions have had on nurturing a state of peaceful coexistence. Once a holistic understanding of the situation on the ground was grasped, a visual toolkit of the various landscape-based elephant-friendly strategies was curated. The intention behind the creation of a visual toolbox was to make available a quick reference that could inspire other tea plantations in the state, and the country, to also adopt sustainable landscape strategies that nurture a state of peaceful co-existence between elephants and humans.

3. Results and Discussion

3.1 The Grim Reality of Elephants in Assam

The Indian state of Assam harbours 5,719 elephants, the highest population of wild elephants in the country after Karnataka (Ghosh, 2018). This positions the state as India's prime elephant range and a crucial epicentre for elephant conservation. However, the elephant's survival in the state's prime habitats presents a grim reality. As touched upon in the introductory passage, against the backdrop of an ever-shrinking habitat and chocked corridors connecting their fragmented habitats, elephants are driven by hunger and thirst to stray into villages and raid crops. Owing to the adjacency of the tea plantations to forest habitats, the tea-growing community's villages often fall prey to wandering herds of elephants. Although the elephants only want to reach the paddy fields without any confrontations with the villages of tea-growing communities between the forest cover and the fragrant rice fields (The Sentinel, 2021), the situation of losing valuable paddy harvest after an entire year's hardship prompts these villagers to undertake measures that lead to confrontations. Villagers pelt stones and hit the elephants with sticks to

implements strategies to safeguard the entirety of the plantation from elephant wanderings and destruction. Plantations install barbed/razor wire or electric fencing to keep elephants out of their plantations, but in actuality, end up threatening their very lives. Electric fencing has led to elephants being electrocuted, while barbed/razor wire fencing has resulted in elephants succumbing to septicaemia. The drainage ditches of the tea plantations are another death trap for elephants. As the name suggests, these ditches are created for agricultural reasons to keep the roots of the tea plants from rotting. There is no elephant-detergent intention behind its existence. Nonetheless, its articulation into deep trenches with steep edges results in calves stumbling into them, getting stuck, injuring themselves and sometimes dying (Fobar, 2021). The surviving elephants, constantly suffering wounds and obstructions, become irked at the slightest provocation (Akhtar, 2021). This, in turn, causes a high number of human fatalities. In the tea plantation district of Udalguri, Assam's hotspot of human-elephant conflict, from 2001 to 2020, around 345 people and 206 elephants have lost their lives owing to human-elephant conflicts (Akhtar, 2021). Figure 3 illustrates the various instances of elephant fatalities upon encountering humans.

Faced with such facts and statistics, one is compelled to wonder why strategies that have proven to cause confrontation and deaths on both sides persisted? The logic for it can be found in the policy approach of government establishments. For years, State Forest Departments have relied upon deterrent methods for conflict mitigation, focusing primarily on protecting human lives and property rather than the elephants. As such, the forest departments promoted measures such as chasing problem elephants, using olfactory and auditory deterrents, and constructing physical barriers among villagers and tea plantation management. For instance, the big buzzword in the 80s and 90s was EPT or Elephant Proof Trenches dug to keep the elephants out (Roy, 2015). These are the same trenches where elephant calves often succumb to their deaths. Through the 2010 ‘Gajah Report’ and the 2017 ‘Guidelines for Management of Human-Elephant Conflict’, the Ministry of Environment, Forest and Climate Change sought to diverge from the forest department's deterrent approach and advocate for landscape level protection and management strategies. However, their 2020 advisory document titled ‘Best Practices of Human-Elephant Conflict Management in India’ dismissed their earlier sustainable advocacy. The 2020 document cited anti-elephant deterrent measures practised by forest departments as best practices to be followed, despite those measures being validated time and again as precursors for aggravating conflicts and causing fatalities. As pointed out by various leading wildlife conservationists reviewing the recent government directive, without considering the elephant's behaviour and ecology and addressing the root cause of conflict, i.e. habitat loss and fragmentation, band-aid, ad-hoc solutions’ will not be effective (Bindra & Rawat, 2020).

Figure 3. *Elephant fatalities in Assam upon venturing into human spaces.*

3.2 What Elephants Need?

It is thus imperative to recognise the needs of the Asian elephants to strategise solutions that would nurture a peaceful co-existence in our shared terrestrial ecosystem. The first facet to be understood is the Asian elephant's habitation pattern and preferences. Asian Elephants are an 'edge species' dependent on forest edges or ecotones (Fernando, 2015). They prefer to spend much of their time in tall, mature forests, with frequent forays into grasslands to satisfy the needs of being a mega- herbivore. Additionally, Asian elephants are long-range animals that migrate from one habitat to another within their home ranges. Asian elephants in North-east India have exhibited a home range of over 4,000 square kilometres. Such a large forested area to designate as a protected elephant habitat for Assam's elephants no longer exists. But Elephants have a long life span, and therefore, despite the forests not being there, they would return to their once primary habitat in which human beings now live, resulting in conflict (Rahman, 2021). These return journeys to their primary habitats have another crucial factor that requires consideration. Young calves in a herd determine the pace of the herd and duration of stay at various places along their route. Calves take smaller strides than their adult counterparts and require frequent rests on their journeys. They also need assistance feeding and bathing, leading to the herd having to rest for hours at a stretch at a particular place. Pregnant elephants often give birth in the canopy covers of the tea estates that fall on their route. In such cases, herds move from the birth location only the next day, and even then, they have to wait for two days for the newborn to have the strength to join the herd (Amarendra & Bhuyan, 2022). Adequate rest spaces in the elephant's migratory route become essential for cow elephants and their newborn calves. Figure 4 depicts the young calves struggling to rest while on journeys. With the calves being at the centre of a herd's priority, adult elephants become violently protective when humans disturb the resting intervals of a herd with calves.

Figure 4. *Young calves require safe spaces of rest in their migratory route.*

The second facet to be understood is the Asian elephant's dietary necessities. Asian elephants in India spend up to 19 hours a day feeding due to their daily nutritional requirements of almost 150 kilograms. Their dietary consumption comprises a large proportion of grass and substantial amounts of leaves, tree stems, tree barks, and roots. They tend to prefer grasses as they grow in abundance; hence, they are easy to gather and have few secondary compounds (Fernando, 2015). The non- availability of grasslands in

such as rice and banana. As mentioned in the preceding section, when elephants venture out of their forests, they seek food, not intentionally getting into confrontations with humans. If the elephant's food security is taken care of, the entire problem of human-elephant conflict is averted. Hati Bondhu Foundation, under the visionary stewardship of Mr Pradip Bhuyan, has been able to make such a scenario a successful reality. Through their Elephant Habitat Enrichment Program, Hati Bondhu has initiated plantation of approximately 70 acres of barren land at Hatikhuli and Nonoi; which lie on the frequent migratory route for wild elephants; with favourable grass species such as Tiger broom grass *Thysanolaena)*, Tora *(Alpinia nigra)*, Napier *(Cenchrus purpureus)*, and fruit trees such as elephants apples *(Dillenia indica)*, and Jackfruit *(Artocarpus heterophyllus)* - to supplement the nutritional requirements of elephants (Amarendra & Bhuyan, 2022). In another two sites of Ronghong and Thuramukh, Hati Bondhu has sensitised local communities to initiate paddy plantation for elephants on community land - thereby creating a 'Food Buffer Zone' to keep elephant herds strategically contained in a demarcated area for a short period and away from primary crop fields during the harvesting season (Amarendra & Bhuyan, 2022). While strategies such as addressing the food security of elephants are conventionally unthought of, Hati Bondhu, through their programs, has exhibited that remedies for reducing crop- raiding behaviours lie in being able to address its causes; their need for food (Amarendra & Bhuyan, 2022). Figure 5 illustrates the strategies adopted by Hati Bondhu to create food security.

Figure 5. *Hati Bondhu is creating food buffers for wild elephants in Assam.*

The final facet to be understood is the Asian elephant's water requirements. Asian elephants prefer being close to freshwater bodies as their body requires them to drink water at least once daily (Fernando, 2015). As a result of their intensely fragmented habitats, most elephants in Assam have to make regular journeys from their place of stay/rest to the sources of water. Their traditional water sources have become engulfed by human settlements and infrastructure, leading to confrontations and deaths. During the 2017 droughts in Karnataka and Tamil Nadu, dehydrated elephants strayed into villages around reserve forests in search of drinking water and, in the process, damaged crops (Goswami, 2017). Similarly, despite frequent deaths in Assam, elephants regularly risk dangerous passages over roadways and railway lines to access water bodies (Amarendra & Bhuyan, 2022). Hati Bondhu, within their program of paddy plantation for elephants, has incorporated several ponds that provide water security to the elephants. The foundation undertook this strategy to give the elephants all their requirements within one standard buffer zone,

provide water to wild elephants.

Figure 6. *Hati Bondhu is creating water security for wild elephants in Assam.*

3.3 Nurturing a state of coexistence

Elephants are intelligent animals who adapt quickly to temporary mitigative measures (Sharma et al., 2022). Years of experiencing elephants wandering into tea plantations have made the plantation management aware of this characteristic. Plantation management is also mindful that elephants are compelled into human spaces due to the necessities of food, water, and refuge while on their migratory routes. While many plantation managements remain oblivious to the need for sustainable solutions that address the root cause of the conflict, quite a few managements in recent years have begun to act upon the intrinsic necessities of the elephants. These plantations have pioneered the implementation of landscape-based strategies that break away from the conventionally prescribed anti-elephant ad-hoc fixes and embrace an elephant-friendly stance. Their solutions address the issues of food and water security, along with recognising the potential for creating safe spaces and passages for elephants within the extents of the tea plantations. These strategies adopted by the tea plantations to create an elephant-friendly have been illustrated in figure 7 and discussed in the subsequent points:

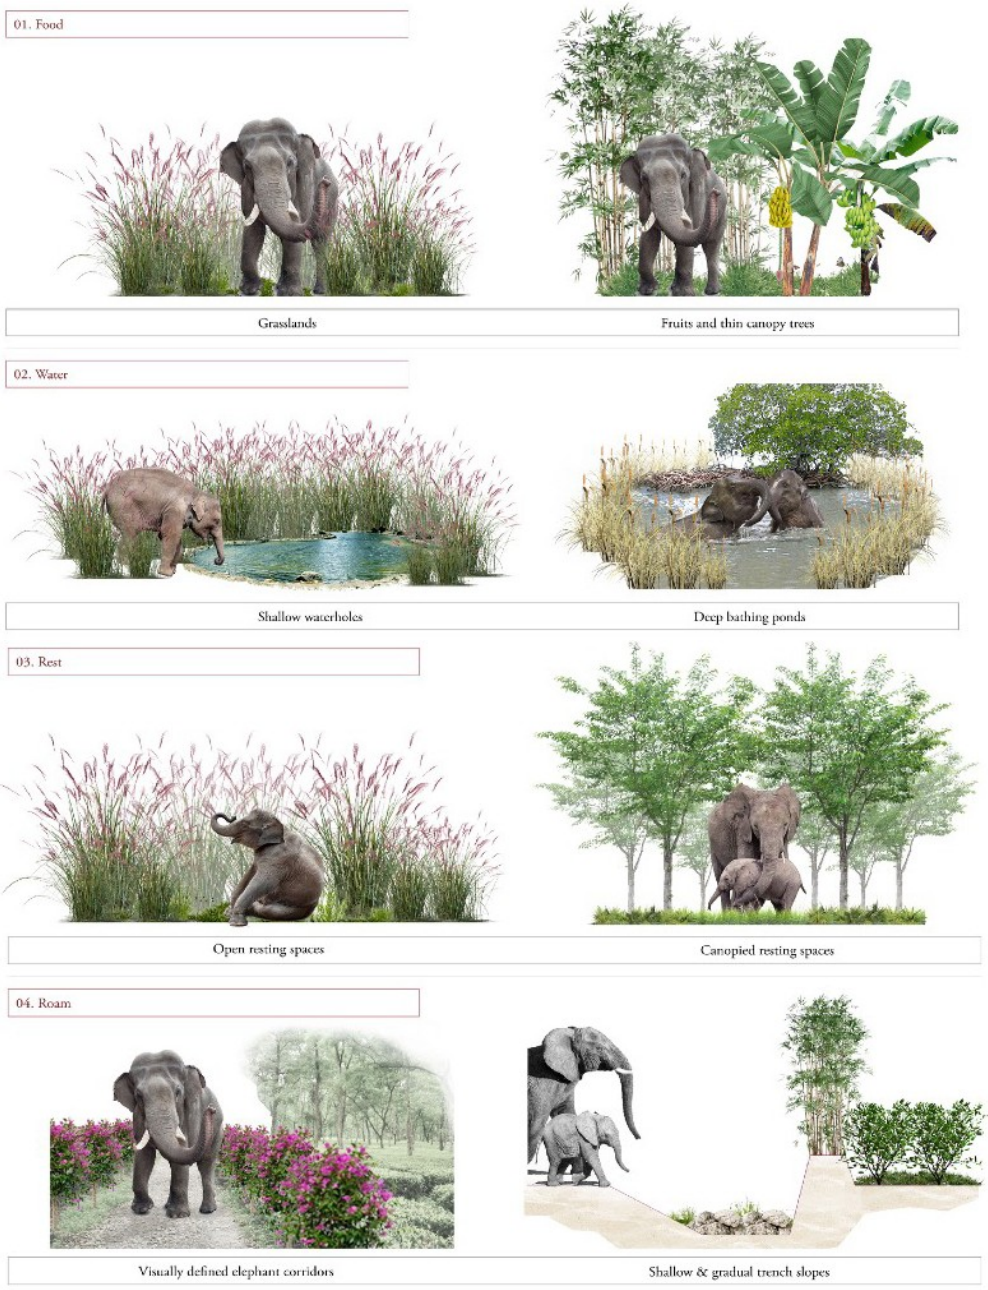

Figure 7. *Visual toolbox of landscape-based strategies for conflict mitigation in Assam.*

Elephant Buffers: Small tea-grower, Tenzing Bodosa's 40 acres of tea gardens have incorporated buffer zones planted with vegetation that elephants are fond of, from elephant grass and elephant apples to bamboo and starfruit (Sunder, 2020). In addition, his tea gardens also maintain forest patches where elephants come to take refuge during the day. There have been instances of cow elephants coming to give birth amidst the plantation's buffer and returning to their forest habitats. Similarly, McLeod Russel's plantations in the Mangaldoi circle have preserved clusters of shade trees within the plantations, where cow elephants and their newborn calves usually seek refuge.

1. Water holes: Tenzing Bodosa's tea gardens have created water holes for elephants to drink water during the summer. In Nonaipara Tea Estate, temporary water holes are regularly filled with water when the natural water holes are found running dry in the summers. Unlike in the first two cases, McLeod Russel's plantations in the Mangaldoi circle have created large water bodies that can cater to the year-round needs of the wandering elephants on the plantations. Both young and adult elephants can be seen drenching in these water bodies during days of oppressive heat.
2. Elephant Passages: Estates lie on historic migratory passages of elephants in Assam. To allow free movement, Apeejay's Sessa Tea Estate in Sonitpur has begun converting the route used by elephants through the tea estate into a formal elephant corridor, through which they can move undisturbed and unobstructed. In Nonaipara Tea Estate, the management has removed bushes to clear the path for the elephants. Along this path, bright bougainvillaea plants that flower through the year have been planted to provide visual cues to the labourers and the elephants of the designated migratory corridors. The Nonaipara tea estate has also modified the plantation's deadly trenches to be more conducive for elephant calves. The slopes into the drains have been made U- shaped from the traditional sharp V-shaped steep drop (Saran, 2021).
3. Harmless Fencing Solutions: For areas within a tea plantation that require elephants to be kept out, sustainable fencing solutions have come into use. In Apeejay's Sessa Tea Estate, bio-fencing is being implemented using thorny bamboo easily grown in Assam. Natural in their compositions, these fences do not induce wounds that lead to septicaemia deaths. Nonaipara Tea estate, on the other hand, has erected a solar-powered fence along its northern boundaries. Solar fences give a mild electric shock that is not lethal to the elephants.

While these solutions have been implemented in a few tea estates as opposed to the hundreds of tea plantations in Assam, they have been highly successful in averting cases of confrontations and, most importantly, deaths. Solutions such as defining corridors for movement have slowed the elephant's advances through the garden. They have been reported to pad quietly along these corridors, causing no harm to the tea plants and entering the jungle areas (Saran, 2021). Solutions such as buffers for food and refuge, along with waterholes, channelise the herds of elephants to designated zones within the garden. Elephants straight away go to these areas instead of straying into human habitations. The tea garden communities have also become wiser to not go into these spaces created for elephants, ensuring that elephants within the tea estates can remain undisrupted and unprovoked.

4. Conclusions

Elephants are intrinsic to India's cultural and religious identity. With a total population of 27,312

position of being able to become a safe haven for these regal beasts. However, historical and contemporary factors have confined India's elephant population into fragmented habitats with limited food and water requirements. The right of passage between these fragmented habitats to seek food and water is also denied to these elephants as a result of callous policy decisions when it comes to planning land use and land development. In particular, Assam's forests and elephants are reeling under increasing encroachment pressures from government-led infrastructure development, private construction, and agriculture. This has pushed the elephants into circumstances of extreme fragility and fatality when it comes to their survival. The death of 825 elephants due to human-elephant conflicts is not compensable. Each life lost strikes a nail into the coffin of the species' very existence in the country.

Against this grim backdrop of losing many elephants each year to episodes of human-elephant conflicts, the tea plantations of Assam have come to the limelight as effective niches for elephant conservation. Elephants already perceive and use tea plantations as stepping stones as they navigate through a human-dominated landscape. By incorporating an understanding of the elephant's survival necessities and thereby addressing those through landscape-based strategies, tea plantations can be spatially and ecologically intervened to become a crucial stepping stone in a larger, more elephant- friendly landscape. Tea plantations spearheaded by environmentally sensitised leadership have already embraced this sustainable stance. Case studies of the tea gardens that have broken away from the conventionally prescribed ad-hoc fixes have exhibited positive results in averting human-elephant conflicts. Elephants have become calmer inside the precincts of these tea plantations, and the growing tea community has also been able to shed their fear and insecurity to develop positive attitudes toward their presence in the same landscape.

The current elephant management policy of the country is still aligned with protection within reserve areas and the implementation of deterrent measures when elephants stray into human habitations. Within this backdrop, the elephant-friendly efforts pioneered by the tea plantations of Assam have exhibited the need for visionary leadership and courage to diverge from the prescriptive to defy the prevalent status quo and establish much-needed sustainability paradigms. These pioneering cases have showcased that management must be courageous to uphold their environmental consciousness despite considerably greater financial investments than conventional methods. The management is additionally required to have the courage to work towards evolving these solutions even when they fail in the pilot phases. While these positive cases from the tea plantations of Assam have initiated a tangible momentum towards seeking sustainable paradigms for co-existing with elephants, complacency is fatal now. These cases are one in a hundred, with most stakeholders having the power to make impactful changes still doing nothing to address the elephant's basic survival necessities. The current research can be developed in the near future to address the qualms of plantation management in shifting toward these landscape-based strategies. By presenting statistics such as muted elephant encounters, positive co-existence perceptions in intervened tea gardens, and financial damages saved against the one-time investment made towards these interventions, the current research could strengthen the case for incorporating these landscape-based strategies in more tea gardens in the state. With only 5,719 elephants surviving in the state of Assam, if these sustainable solutions are not amplified, elephants will continue to be forced into confrontations that would lead to their eventual annihilation.

Source Tracking of Fecal Contamination in Northern Oligotrophic Rivers

Dr. Sharon Maes, Prof. Monica Odlare, Prof. Anders Jonsson

Mid Sweden University, Östersund, Sweden

Abstract

The naturally oligotrophic rivers in northern Sweden are generally characterized by a low pollution level. However, an increasing trend in *E. coli* contamination has been observed in the most upstream catchment area of one of the large rivers of Norhtern Sweden. This change in microbial water quality will have a severe negative impact on the ecosystem, wild animals, visitors, inhabitants as well as indigenous people dependent on the land for their daily income, such as Sami herders. To limit or prevent the discharge of fecal pollution into the river system and also to estimate the danger that this contamination can pose to human health, it is important to know the source of this contamination. Based solely on structured water sampling, it is still very difficult to pinpoint the sources of fecal pollution. Therefore, a combined analysis of eDNA and microbial source tracking of *E. coli* isolates from river samples was performed to identify the source of fecal pollution in the research area.

E. coli isolates were collected from water samples taken along the tributaries Enan and Handölan. Simultaneously, eDNA samples were collected on the same locations. Additionally, fecal and sewage samples were taken to collect *E. coli* isolates with a known host source being either human, beaver or reindeer. Also, sequences from genomic *E. coli* DNA originating from human (obtained from NCBI and University of Alberta, School of Public Health) and from beaver (obtained from University of Alberta, School of Public Health) were collected and included in the study. *E. coli* isolates were used for the amplification of three Intergenic Regions and subsequent analysis of Single Nucleotide Polymorphisms to identify host-specific genetic markers in the *E. coli* genome. eDNA samples were subjected to metabarcoding targeting mammal DNA to determine the relative species abundance in the water samples.

The *E. coli* prevalence in the research area varies between <1 and 210 CFU/100mL and is dependent on e.g. sampling location (possible point sources), time (tourist intensity and area specific events such as reindeer calve marking) and weather (precipitation, river flow, UV radiation). A library containing the data from *E. coli* isolates that are known to be originating from the species human, beaver and reindeer was developed and used to identify the host source of the *E. coli* isolates collected from water samples. Consequently, *E. coli* isolates could be identified as originating from human, beaver, reindeer or a different mammal species. Results from the eDNA analysis provides information about the relative abundance of mammal species on a certain location. Although these results don´t provide a direct link to the presence or absence of fecal pollution by these species, it can provide interesting knowledge about the source of fecal pollution when combined with the *E. coli* prevalence data from the same sampling locations and times.

Transdisciplinary, Global, Important, and Challenging: Reflections on ocean climate finance projects in the sustainable development agenda

Dr Sebastian Thomas[1,2], Angela Bruckner[3], Dr Thu Ba Huynh[4], Carmen Munhequete[5], Yunae Nam[6], Arpana Pratap[7], Dr Larissa Shnayder[8]

Abstract

More than a third of the total human population lives within 100 kilometres of an oceanic coast. The Intergovernmental Panel on Climate Change (IPCC) estimated in 2019 that 680 million people were living in low-lying coastal areas and projected this number to exceed one billion by 2050. Whether living in cities or smaller communities, people rely on the ocean to provide food, resources, energy, oxygen, livelihoods, recreation, spirituality, and other essential goods and services. As the human population continues to grow, however, its impacts on the ocean, both in coastal zones and further out in the high seas, are increasing as well. In combination with climate change effects including ocean acidification, sea level rise, and global warming, human activities are causing depletion of marine fisheries, deterioration of water quality, deoxygenation, loss of biodiversity, death of coral reefs, coastal erosion, and other negative outcomes. The ocean is vital to communities and the global economy; the ocean is in crisis.

The 2030 Agenda for Sustainable Development includes 17 sustainable development goals across five critical dimensions: people, prosperity, planet, partnership, and peace. Within this framework there are many opportunities for ocean-focused mitigation and adaptation projects, and multiple public and private instruments that can provide finance for such initiatives. However, an analysis of the Green Climate Fund – one of the most important finance vehicles for climate change mitigation and adaptation initiatives, particularly in developing nations – finds that only around 2% of funds are being directed to ocean-related projects and programs.

This paper presents data on the nature, distribution, types, and impacts of ocean-related climate finance (OCF) and provides reflections on the state and trends of OCF following a global research and capacity building initiative conducted across multiple Commonwealth countries in Africa, the Pacific, and the Caribbean. The analysis finds that there remain substantial gaps in understanding of ocean climate change issues across government, industry, and community sectors. Further, there are specific challenges and opportunities for ocean climate finance in the sustainable development agenda, including the need for and difficulty of transdisciplinary initiatives, the importance of global links and partnerships, and potential for paradigm shifts through new technologies and approaches.

A Healthy Environment and Human Development: Is it possible to achieve both objectives?

Dr Gustavo Nicolas Paez Salamanca[1], Urvana Menon[2], Luisa Vargas[3]

[1]WWF Myanmar, Nay Pyi Daw, Myanmar. [2]WWF Myanmar, Yangon, Myanmar. [3]Independent, Bogota, Colombia

Abstract

It is becoming increasingly evident that one side of this debate is driven by economic interests focused on short-run economic gains, without care for the way in which wealth is distributed, sustainable goals, or opportunities for future generations. However, if we care about the sustainable improvement for people and their livelihoods, especially those who are the most vulnerable, we realize that healthy environments and human development are not competing objectives – they are one. As many countries rapidly deplete their natural resources, caring for and investing in these resources in Myanmar is imperative to create safety nets that guarantee the basic needs of the people of Myanmar. WWF-Myanmar's strategy takes a holistic approach to improving the lives and livelihoods of those living today and aims to protect the natural environments that will support the lives and livelihoods of generations to come.

This report is the first in a series of four reports in which we lay out the theoretical justification for investing in nature and the challenges to doing so. Following reports will review the current state of Myanmar's natural resources, its governance and legal framework for protecting natural environments, and how to begin implementing solutions. The current report is divided into four chapters that integrate economic, environmental and social elements into the development discussion and provide a framework to evaluate the importance of investing in nature to foster sustainable development. Although the examples are based on Myanmar, the concepts presented in this report are valid for any development discussion.

The first chapter discusses the inadequacy of traditional economic frameworks to assess the role nature plays in the improvement of society and recommends analysing development projects based on their capacity to provide safety nets and basic needs. By integrating behavioural and development theories, the chapter summarizes the core development model in a pyramid of needs that can guide policymakers in identifying relevant projects. The second chapter examines the role of nature. Based on a systems' theory perspective, it explains how the different characteristics of natural systems affect livelihoods. The chapter discusses how nature is never static and, by aligning our processes to nature's cycles, how we can improve our resilience to natural and economic crises. The third chapter joins the previous two and explores how concepts such as ecosystem services and nature-based solutions can support our economic and social development. Moreover, this chapter discusses the different types of services that nature provides and how each helps communities progress through levels of development. The chapter concludes by showing how adequate environmental management is a holistic topic that requires a good understanding of ecosystems and their interactions with society. Finally, chapter four discusses how human incentives affect environmental protections, focusing on the role of power groups and governance arrangements.

Cultural Services of City Parks – measurement and improvement options

PhD Noémi Csigéné Nagypál

BME, Department of Environmental Economics and Sustainability, Budapest, Hungary

Abstract

City parks are important elements of urban green infrastructure, contributing to the sustainability of local communities and providing ample services. They provide services of local and global importance: for example, they are important from the aspect of climate change adaptation − by local climate regulation − and mitigation by carbon sequestration. The relevance, measurement and improvement options of cultural services are assessed in case of city parks. The paper consists of two major parts: an international literature review about the calculation of the total economic value, using various methods, focusing on cultural values, as well as the introduction of the results of two online surveys prepared in Budapest. The literature review provides a comprehensive overview of valuation methods: revealed and stated preference techniques, presenting their benefits and limitations. Two city parks of different attributes – location, size, history, functions – have been selected for the online survey, one located in an inner district and the other situated in a relatively green, outer district. The attitude, knowledge, preferences, and behaviour of local people are assessed, including the importance of the various elements of total economic value – non-use, option and use values – and ecosystem services for them and their willingness to pay for the maintenance of the two parks. The results for the two parks are compared, identifying common elements and specialties. According to the Common International Classification of Ecosystem Services, recreational value belongs to the cultural value of the major categories, but local citizens consider it as a narrower part of the total value. Use value is especially important for those who visit and use the parks regularly. It is concluded that cultural value can be measured using various methods and it can be enhanced at a relatively low cost, by awareness-raising among others. The more conscious use of city parks may increase their contribution to local level sustainability.

Factors Affecting the Use and Value of Traditional Ecological Knowledge in Conservation and Management of Savanna Ecosystem Services among the Rural Communities of Capricorn District Municipality, Limpopo, South Africa

Miss Sibongile Moloise, Dr Abraham Matamanda

University of the Free State, Bloemfontein, South Africa

Abstract

Over the years, people have formed an intimate relationship with their immediate physical environment. They have developed a body of knowledge on ecosystems and their services since the beginning of human existence and passed down through generations known as Traditional Ecological Knowledge (TEK). This knowledge is incorporated into traditions, cultural practices, and lifestyles. However, the introduction of urbanisation and western science and culture have resulted in TEK and ecosystem services degradation. Furthermore, the academic world undermines TEK, considers it non-scientific, and disregards TEK's conservation policies and plans for ecosystem services. The research investigates the existence of TEK, its status, and how it is or can be applied in the conservation and management of ecosystem services in rural communities of Capricorn District Municipality in Limpopo province. Primary data of the study is accumulated through in-depth interviews and observations from a sample population of 18 years old plus people who directly depend on ecosystem services in rural communities. The expected results of the study are that TEK was dominantly used previously for the conservation and management of ecosystem services.

Conversely, its effect has declined in communities that are becoming developed and westernised. The proposed abstract relates to SDG 11, Target 11.4, SDG 15 Target 15.1, Target 15.4 and Target 15.9. Environmental, economic, and social factors are most important for sustainable development and courage; hence development should not come at the expense of either of the three. Instead, it should enhance them. This study assesses how evolution has affected cultures and the natural environment. Therefore, the importance of culture and its use to conserve the environment and provide humans with basic needs explored in this study relate to the conference's topic. Conservation policymakers need to understand the relationship between man and the environment and bring environmental management plans and strategies that allow people to sustainably benefit from nature, which can be achieved through cultural practices and traditions.

Impact of Rural Transformation on Land use and Ecosystem Services in Three "Real Labs" in China

Dr. Suili Xiao, Till Fuegener, Prof. Wolfgang Wende

The Leibniz Institute of Ecological Urban and Regional Development (IOER), Dresden, Germany

Abstract

China is undergoing rapid changes in rural areas where new opportunities linked to urbanization processes and rural revitalization. Rural transformation (e.g. urbanization, industrialization, agricultural modernization as well as ecological conservation) leads to a shift in land use which has had a major influence on vegetation and further impact on biodiversity which underlies all services provided by ecosystems that are crucial for human well-being. Though empirical research in three "real labs" in Huangyan-Taizhou, supported by remote sensing analyses and GIS tools, as well as matrix approach, land use and land cover change, green vegetation condition (NDVI) and ecosystem services (especially biodiversity) were analyzed spatially and temporally from 1992 to 2020. Our findings indicate that, firstly, urban areas increase dramatically in the new industrial area at Xinqian Smart Molding Town with 394 % increase, followed by Beiyang Agricultural Township with 143 % and Jianyang Wetland Park with 595 %. Simultaneously, forest area in these three study areas decreased by 69 %, 9 % and 49 %. Secondly, urban expansion has led to a loss of vegetated land in all three research areas during the past three decades. The biomass and density of vegetation, estimated through NDVI calculations, has slightly increased in Beiyang Town. Still, the values of mean and median NDVI are slightly decreasing in Xinqian Molding Town and Jianyang Wetland. Thirdly, the supply of ecosystem services, including biodiversity in each research sites is developing downwards. Whereas the research site of Beiyang Town is showing the least change in ecosystem service supply, Xinqian Moduling Town band Jianyang Wetland Park are experiencing a strong decline in ecosystem service supply during the research period. Main drivers of relevant changes and different transformation patterns are also discussed. The results and detected impacts of rural transformation on biodiversity and ecosystem services might be employed to improve sustainable development strategies, spatial planning, and biodiversity conservation.

Rational Management of Veterinary Antiparasitic Treatments in the South-east of France

Doctor Ilyes Bouasla[1], Professor Philippe Jacquiet[2]

[1]Institute vétérinary sciences, Constantine (khroub), Algeria. [2]National school vétérinary, Toulouse, France

Abstract

The ecotoxicity of veterinary antiparasitic treatments, studied for a long time, and the

development of resistance against several families of antiparasitic molecules lead to thinking about the proper use of antiparasitics, in order to reduce their ecological impact while controlling the health and economic issues within herds. The study presented here explores these notions within the framework of the support of a group of nineteen breeders from two French departments (Gard and Hérault). They are engaged in a process of reasoned management of the parasitic risk through the respect of a notebook of environmental protection burden, relative among others to the conservation of threatened species such as the ocellated lizard, Timon lepidus. These breeders practice various activities as well as different types of breeding (sheep or beef cattle, Camargue cattle, dairy goats, racehorses). Semi-structured interviews with the breeders made it possible to describe their practices and to understand how they integrated the reasoned management of the parasite risk into their strategy. Coprologies were carried out in order to determine the rate of infestation of herds by gastrointestinal endoparasites and to recommend targeted treatments using molecules that are not ecotoxic for the environment or/and management of the parasite risk into their strategy. Coprologies were carried out in order to determine the rate of infestation of herds by gastrointestinal endoparasites and to recommend targeted treatments using molecules that are not ecotoxic for the environment or/and effective alternatives, of which the strategy must be adapted according to the type of breeding and species. The majority (80%) of breeders are moving towards a reasoned strategy without necessarily being aware of it since they rarely treat their animals and are generally concerned about applying the right treatment methods. Nevertheless, they seem to need close support for the diagnosis, the choice of the time of treatment and the molecules to be used as well as for the management of animal movements between plots. The study shows the essential role of practicing veterinarians in this type of approach. However, awareness raising and training must be organized in order to encourage their involvement.

Soil Fungi as a Tool for Carbon Sequestration in the Mitigation of Climate Change

Mr Tijjani Mustapha[1], Mr Nura Jibo[2]

[1]Federal University Dutse, Dutse, Nigeria. [2]African Climate Change Research Centre., Dutse, Nigeria

Abstract
Fungi are a group of organisms that can be present in almost every part of the ecosystem. Soil inhabiting Arbuscular Mycorrhizal (AM) fungi are very important group with wide range of ecological importance that form symbiotic relationship with over 80% of vascular land plants. AM fungi are known to have crucial influence in the recycling of organic matter in the soil. They sequester soil carbon by assimilating atmospheric carbon from plant hosts to harness it biologically for the development of their body structure (Hyphae). AM fungi lock carbon into the soil by rhizodeposition or soil aggregate formation as well as their role in carbon fluxes between the plants and the atmosphere, thereby preventing climate change by hindering the carbon from re-entering into the atmosphere.

Methodology:This paper uses quantitative and qualitative methods in analyzing Arbuscular Mycorrhizal sample data collated and Bio-assayed under different climatic condition. It utilizes a cost-efficient technology such as pot culture method for large scale commercial production of AMF inocular.

Expected results:With over 500 million farmers cultivating about half billion hectares of land globally, the role of AMF can be utilized through modern technologies to incorporate the use of these microbes as a means of biological carbon sequestration. They increase agricultural productivity and transformation of agricultural fields in to carbon sink.

Conclusion: Arbuscular Mycorrhizal can be used as bio-fertilizer in sustainable agriculture. An assessment of the performance of edible mycorrhizal mushrooms using bioassay and pot culture method can identify the most suitable species with the best physiological ability in soil carbon sequestration, which reduces excessive and uncontrolled use of chemical inorganic fertilizers. The levels of environmental pollution are also minimized.

Key words: Mycorrhizal Fungi, Carbon Sequestration, Climate Change Mitigation, Arbuscular Mycorrhizal, Soil.

Assessing Farmers' Perception of Climate Change and Adaptation Behaviour: A study of Kashmir valley, Western Indian Himalayan Region

Mir Khursheed Alam, Shyamasree Dasgupta

Indian Institute of Technology Mandi, Mandi, Himachal Pradesh, India

Abstract

Farmers' livelihoods in the Indian Himalayan Regions (IHR) are under direct exposure to and are subject to widespread risks arising from multiple climatic hazards, climate change and variability. While 'adaptation' is the process of adjustment to actual and/or expected climatic conditions in the long term, in the absence of available information, infrastructure, and socioeconomic ability, farmers often adopt certain 'coping' mechanisms that provide them cushion only against short-term losses. A holistic understanding of the available adaptation processes, and their determinants are, therefore, instrumental in developing well-targeted and effective adaptation strategies. This study aims to understand the nature of farmer responses; their determinants; and the scope of institutional/planned adaptation and policies, in the face of climate hazards, and climate change in the Kashmir Valley. The analysis is based on cross-sectional survey data of 648 (apple and rice) farming households in four districts that correspond to the cold humid and warm subhumid agroecological zones in Jammu and Kashmir. Results demonstrate that majority of the farmers believe in climate change (93%) and are also cognizant of local-seasonal variation in temperature and precipitation regimes as 94% of them have observed it more pronounced in the last decade. Farmer responses are largely confined to 'autonomous coping' with higher uptake, with a few planned adaptation measures in place with a minimal uptake. Adjusting apple farming practices (such as harvesting, pruning, grafting, and spraying) are some of the prominent farm-level autonomous-coping strategies in response to reducing the crop damage due to inter-annual and inter-seasonal climate variability and extreme weather events. Farmers opt for crop transformation and variety diversification, and water-use management adaptation measures in response to long-term climatic impacts. Despite the scope, there exists a significant planned adaptation gap, given the minimal provision of adequate infrastructure, early warning, agriculture credit, and crop insurance. An analysis based on Multivariate Probit Regression models also suggests that recurrent multiple hazards experience constraint autonomous adaptation of farmers (related to crop transformation and variety diversification) and induce them to adjust farming practices and water use management measures. Farm, household, economic and institutional determinants play important role in determining the kind of measure that the farmers are likely to opt for. The outcomes of the study suggest the need for an enhancement of planned adaptation mechanisms that would prove essential not only to complement community-based and autonomous adaptation, but also crucial for the achievement of other sustainable development goals such as sustainable natural resource management, and food and human security. The study emphasizes resilience-building adaptation interventions that target farmers with potentially low adaptative capacity, such as aged and experienced farmers, farmers without/low formal education, fewer income sources and limited connectivity to the district headquarters. Effective institutional mechanisms such as enhancement of investment in agro-infrastructure, alternative livelihood options, integrated farming, and robust early warning system are key to reducing the long-term risk and shaping climate-resilient communities in the Himalayan region

Assessment Framework of the Transport related Carbon Mitigation Options for Efficient Fleet Management

Dr. Tibor Princz-Jakovics

Department of Environmental Economics and Sustainability, Faculty of Economic and Social Sciences, Budapest University of Technology and Economics, Budapest, Hungary

Abstract

The aim of this research is to provide an assessment framework for the evaluation of the transport related carbon mitigation options to increase the efficiency of the fleet management planning tools. Enterprises usually operate integrated and professional fleet management systems and plan carefully the renewing options of their fleets. However, mitigation of the emissions by the road vehicle fleets should be accelerated, because the contribution of the transport sector to the total carbon emissions (including private and public fleets) is significant. Energy consumption of the road vehicles can be calculated by the specific fuel consumption patterns and operational data series for the fleets. The observed changes in the size and composition of the fleets are mainly reflect to the tendencies that the newly purchased electric and hybrid vehicles partially replaced the vehicles powered by internal combustion engines. Rationalization of the vehicle use can significantly reduce mileage and carbon emissions, however in some cases the possibilities for lower utilization of the fleets are limited and determined by the profiles of the companies or organizations.

Reduction of the transport related emissions can be achieved by increasing the share of e-mobility options for higher level efficiency and alternative propulsion vehicles, like hybrid or pure electric vehicles are preferred to be used. Based on the planned hybrid or pure electric vehicle purchases the acquisition costs are calculated as one of the major elements of the total cost of ownership. Operational costs can be optimized if solar panel energy production is available for charging on site. The unit cost of PV investments is expected to decrease due to declining solar prices and some other additional investments (i.e. the use of battery energy storage) would also increase the efficiency of such investments. Based on the numbers of carbon emission savings and the total gross costs of carbon saving options, the MAC (Marginal Abatement Cost) values of the fleet renewing measures are calculated and can be compared with other options for carbon mitigation. In the planning phase of green vehicle procurement as a measure, it is necessary to consider many aspects together: the level of contribution to decarbonisation, in addition to the aspects of the operational and functional use of the vehicles and the financial possibilities available for fleet renewal. The theoretical contribution of this research is the assessment framework which provides relevant data for fleet operators to be able to examine and calculate the long-term financial and decarbonisation effects of renewing options of their fleets.

The topic of the proposed abstract especially relate to the following SDGs and Targets: 9.4, 11.4, 11.b, 12.6 and 13.3. This research work also relates to the topic of the Conference: “Sustainable Development and courage: culture, art and human rights” by supporting the necessity renewal of the road vehicle fleet to achieve climate conscious mobility culture. E-mobility options provide resource efficient solutions, underly the relevance of SDG 11.4 “Strengthen efforts to protect and safeguard the world’s cultural and natural heritage” and efficiently contribute to the international discussion at the Conference.

Decentralized PV Generation can Satisfy Electricity Demand in Urban Areas: A city case study at Santarém, Portugal

Diogo Dias[1], João Joanaz de Melo[1,2]

[1]NOVA University, Lisbon, Portugal. [2]CENSE, Lisbon, Portugal

Abstract

Climate change has become a matter of major social concern. Reducing the impacts of the energy system, including decarbonization, has become one of the most serious and urgent challenges of our society. Photovoltaic (PV) is becoming increasingly important as an alternative electricity source. However, large PV facilities often create other conflicts with natural and productive areas. Installing PV on rooftops entails higher investment costs and organizational difficulties but has significant long-term advantages: it avoids land use conflicts, enhances energy communities, is more resilient, reduces energy transportation losses, and mobilizes investments by families and companies.

This paper reports the research on the potential of PV generation and its implementation in the city of Santarém, Portugal, a municipality of 62 000 inhabitants. The study focuses on the core urban area of residential and service buildings, with a population of 30 000 (the industrial zone was not included). The study comprehended the following steps: definition of 15 building types based on electricity use patterns; identification of project design criteria for rooftop PV installation, considering building characteristics in the city; delimitation of the study area (968 ha) and its division in large service buildings and 13 homogeneous urban zones; characterization of the large buildings and sample areas of 1 to 3 ha in each urban zone; calculation of PV energy yield in the samples and extrapolation for the study area; calculation of electricity demand by building type and use, based on statistical data; examination of obstacles and

Synopsis of results: in the study area it is possible to install 176 MW of PV on a useful roof area of 99 ha; the estimated productivity is 280 GWh/year, which would avoid 44 kt CO2/year of emissions; Santarém has the potential to satisfy 2.5 times the electricity consumption of residential and service buildings; coupled with energy efficiency measures in the buildings, PV potential could reach 3.0 times the electricity consumption. However, to reach even a fraction of this PV potential, policy measures such as tax incentives, and support at local level, such as technical helpdesks, will be necessary. Current legislation allows energy communities, but existing regulations are biased towards the incumbent large companies. Investments in decentralized PV are viable from an economic standpoint but interested parties (families and small companies) do not possess the necessary technical, organizational, or financial means. This is therefore not a technological or economic problem, but an institutional and cultural problem.

This paper relates especially to SDG targets 7.2 (increase share of renewable energy), 13.1 (resilience and adaptive capacity to climate-related hazards), 13.3 (climate-related education) and 11.4 (protect and safeguard cultural and natural heritage).

Our contribution relates to ISDRS2022 main topic on two counts: PV must be made compatible with the architectural treasures of the city, famed as the Portuguese "Gothic capital"; and we face major educational, cultural and institutional challenges (and certainly much courage) to implement new habits and technologies in old neighbourhoods.

The Impact of Climate Change on Hungarian Agriculture

Kinga Biró[1], Dr. Ottó Toldi[2], Dr. habil. Mária Szalmáné Csete[1]

[1]Budapest University of Technology and Economics, Budapest, Hungary. [2]Climate Policy Institute, Budapest, Hungary

Abstract

In Hungary, a secure food supply, and the basis for the export surplus is provided by a high supply of arable land concerning the population. Hungary has a strong export capacity. In the future, the population is expected to rise and the per capita food supply to decline. Agricultural production is one of the most exposed to the ever-changing weather, with the average temperature rises and changes in rainfall patterns due to climate change. Within Europe, the Carpathian Basin is the most exposed region to climate change, along with the southern countries (Gaál et al. 2014, Hadnagy et al. 2013).

The paradox of the agricultural sector is that the sector can decouple itself from the adverse effects of climate change by becoming more intensive, which, together with increasing the profitability of agricultural production and crop security, increases GHG emissions. Achieving climate neutrality by 2050 will also require a contribution from the agricultural sector, and we can already see that the traditional approach will not achieve the desired results. The goal for Hungarian agriculture is to produce more, realizing its potential and fulfilling its mission in global food markets while reducing greenhouse gas and other pollutant emissions. Hungary has all the tools to achieve this.

In order to gain a better understanding of how Hungarian agriculture will change, how is the exposure of agriculture, and what adaptation measures can be applied, will be examined the scenarios of future GHG emissions from agriculture is being carried out.

Crop production can adapt to climate change by favoring short-duration varieties, which are less exposed to the weather. Species and varieties replacement and the introduction of new and more resistant species, such as batata, are playing an increasing role. Autumn and spring crops respond in opposite ways to climate change. While summer droughts are expected to cause a significant reduction in the average yield of spring crops, the expected wetter winter-spring seasons may even increase the yield of autumn crops. In livestock production, increasing importance will be given to improved feeding, which will reduce methane emissions from cattle. The tools of precision farming and Agriculture 4.0 are gaining ground in crop and livestock production. From the early 2030s, we will increasingly talk about the dawn of the digital age of agriculture, with the launch of Agriculture 5.0 tools - like robotics, drone-based remote sensing, automation, industrial production of proteins, carbohydrates and bio-actives, molecular farming, functional fertilizers, functional food and feed production, bio-herbicides, bio-pesticides -, with near-zero GHG and other pollutant emissions, circular material flows and zero waste. From a climate perspective, agriculture is perhaps the most conservative sector, with no sign of technologies yet that will deliver marketable and significant reductions in emissions. Nevertheless, wherever we are in 2050, agriculture will have two powerful tools at its disposal to achieve climate neutrality: it can even reduce its current emissions by planting carbon-climate crops on marginal land and by basing agriculture on renewable energy.

This proposed abstract aims at dealing with goals by SDG12, SDG13, SDG15.

The Potential for Hydropower Carbon Capture and Storage (HPCCS) - Measuring CO2 degassing from turbines at a medium-sized hydropower station in Northern Sweden

Ms Moa Hallqvist, Associate Professor Andreas Andersson

Mid Sweden University, Östersund, Sweden

Abstract

To limit the human impact on the climate, a shift towards renewable energy systems is a necessity. The increased demand for renewable energy that such a change entails will place great demands on the efficiency of hydroelectric power and its ability to adapt to future climate, both on a regional and global scale. All emission scenarios that limit global warming to 1.5 ° C require that we use large-scale carbon capture and storage (CCS). Although CCS has started to be used at large anthropogenic emission sources, implementation of CCS at natural carbon sources are few. Freshwater lakes and rivers are significant sources of biogenic carbon dioxide and are important parts of the global carbon cycle. Inland waters have been shown to be supersaturated with dissolved carbon dioxide in relation to the atmosphere, leading to CO_2 evasion. Similarly, hydropower plant reservoirs have been shown to be sources of greenhouse gases. The turbulence and drastic pressure changes that occur when the water passes through the hydropower plant turbines will theoretically increase the rate of CO_2 degassing from the water. In this study, we investigate the potential for Hydropower CCS by measuring CO_2 concentrations in the water upstream and downstream of a medium-size hydropower plant (Kattstrupeforsen, Indalsälven) in one of the rivers of northern Sweden. Measurements were performed during September-October 2019 and April-May 2022. The degassing of CO_2 from Kattstrupeforsen was calculated based on the upstream-downstream gradient in CO_2 and measured discharge from the hydropower plant. The results show a daily degassing corresponding to 0.98 t CO_2 in autumn and 1.8 t CO_2 in spring. The linear relationship between the upstream CO_2 concentration and the concentration difference found in this study was used to estimate the annual emissions of CO_2. Annual emissions in a range of 1200-2000 t yr^{-1} were found.

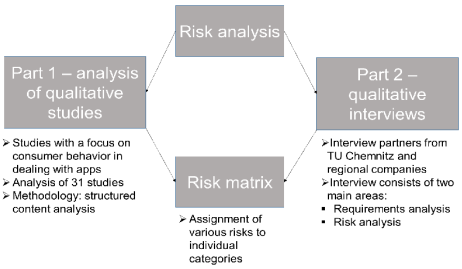
Goal:
Development of a **prototype** of a model-based monitoring system as a **self-learning expert system**, which provides recommendations for action for **facility managers**

Current task: risk analysis

Future tasks:
- Scenario analysis
- Definition of sustainability standards
- Analysis of rebound effects
- Data analysis and evaluation

Methodology



Part 1: analysis of qualitative studies

- Databases: Scopus and Web of Science
- Search string consists of terms of app development and user requirements
- Search string resulted 1866 articles
- 137 duplicates could be identified
- After the screening process in Rayyan, 67 articles could be analyzed
- 31 articles met the inclusion criteria

ELSEVIER

WEB OF SCIENCE

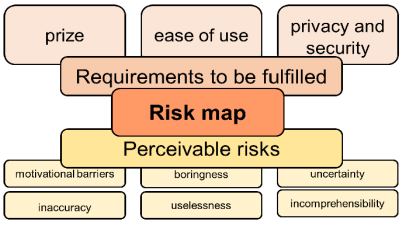
Part 2: qualitative interviews

- The interviews relate specifically to the app to be developed
- Special focus on uncovering possible risks
- The goal of the interviews is to:
  - identify the requirements and risks for the own app,
  - check whether the identified risks from the articles also apply to the app

Results

Risk map

Three main requirements
- The price-benefit ratio
- The user satisfaction, which is divided as follows:
  - Efficiency
  - Quality
  - Usability
  - Learnability
  - Understandability
- Privacy and security, which can be divided into
  - Privacy protection
  - Privacy
  - Access rights to cell phone data



Users identify perceptible risks as follows:
- Motivational barriers
- Boringness
- Uncertainty
- Inaccuracy
- Uselessness
- Incomprehensibility

The Embeddedness of Actors in Brazilian Energy Transition

Introduction

Infrastructure, which has a very strong synergistic component with the environment, is the basic set of goods and services made available to individuals, so that they can integrate socially, with conditions for the development and improvement of life. Energy, among the components of the infrastructure, is perhaps the one with the greatest range of interactions and environmental impacts (Reis & Santos, 2014). Energy settings for developing countries typically present a significant expansion in energy use, and in particular electricity consumption (Fankhauser & Jotzo, 2017).

Economic growth and energy consumption are intrinsically related and tend to increase in emerging countries, especially China and Brazil (OECD, 2015; Saini & Sighania, 2019). The energy industry is facing nowadays a global transition of its well-established sociotechnical system. Efforts to mitigate climate change, new energy sources, and technological developments are in the core of this movement (Berkhout et al., 2012; Ismaeel, 2019; Sovacool et al., 2020).

Brazil already invests in initiatives related to the energy transition. The country stands out on the world stage using three times more renewable sources than the average (EPE, 2021d), though the process is still in motion, and improvements require the involvement of multiple actors.

The analysis of the sociopolitical interactions between the actors involved in the potential changes in the Brazilian electricity industry provides to better understand the role of these actors in the transition paths. It is inferred that it is possible to intuit by a trend of energy transition from an innovation niche or motivated by the exogenous pressures of the landscape from the analysis of the actors involved in the process. Different transition paths may coexist (Ismaeel, 2019). In order to analyze the role of actors and accommodate consumption, cultural, and sociopolitical dimensions, the multilevel perspective framework (MLP) is adopted (Geels, 2002; Marquardt, 2014; Geels, 2018; Ismaeel, 2019).

The guiding question that arises is: Who would be the actors involved in the transition processes in the Brazilian electricity sector?

This paper aims to identify and categorize the actors involved in the process of energy transition in the Brazilian electricity sector in a multilevel perspective (MLP). A literature review was carried out, then a documental case study.

Theoretical Background

The Actor-Network Theory can help to define and coordinate functions within a social structure comprising both social and natural (Callon, 1986; Law, 1992; Callon, 1999; Latour, 2012), as is the case in the electricity sector - especially in Brazil. On the other hand, the Stakeholder Theory offers tools to prioritize the interests (Michell et al., 1997; Rowey, 1997) that will be decisive for the promotion of an energy transition. Therefore, this theoretical background approaches the two theories to address the actors in energy transitions.

Stakeholders in transitions can be investigated regarding the roles they fulfill, such as co-producing knowledge for action, understanding contemporary transitions and exploring sustainable solutions for transitions (Frantzeskaki & Rok, 2018). All actors are potential stakeholders, since it's not always easy to distinguish the interests that deserve consideration (Phillips & Reichart, 2000).

Multilevel Perspective for Sociotechnical Transitions

The transition process can occur both due to the pressure of innovation niches on the socio-technical regime, as well as exogenous aspects, that is, pressures from the broader environment on the regime, as is the case, for example, of climate change in the panorama of decarbonization. Thus, it is fair to say that regime shifts can be either top-down or bottom-up.

Based on the guiding question presented in the introduction, examining the findings in the literature and the documental evidence from the case study, we intend to categorize and place the main actors in the Brazilian electricity sector at the MLP levels, to infer a more bottom-up or top-down energy transition trend. The MLP can help to visualize the organizational field, highlighting the disruptive actors for the promotion of the Brazilian energy transition.

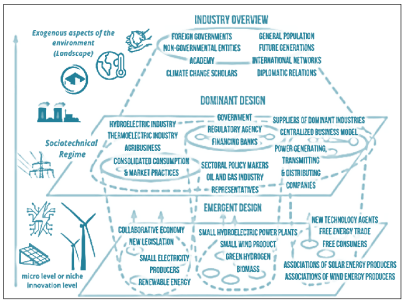
Electricity Industry in Brazil

The formation of the Brazilian electricity sector went through several phases. In the early 1900s, during the so-called "Old Republic", foreign companies established themselves in the country with a strong importance in the establishment of energy policies.

Climate change is a global issue and the fact that Brazil has renewable sources does not exempt it from pursuing decarbonization, besides energy justice and efficiency. In Brazil, many governmental institutions, within their sphere of action, have the competence to formulate and implement policies, plans, programs, and projects that can impact the behavior of energy consumers, as the individual's choice involves several dimensions. There is a need to improve institutional governance for better coordination and communication among different actors.

The actors in the electricity sector can be classified in different ways. The first classification made is the distinction between sectoral economic agents and institutional agents. . The government, regulatory agencies and institutions supporting the planning of the electricity sector can be included in this category, which we can call "Governmental and Institutional Agents".

Economic agents can be subdivided into sectoral and non-sectoral, given that many actors are not directly involved in the sector's activity, but interfere in its course. Three major categories of actors emerged from the case study: i) institutional actors - among which government actors, ii) civil society & financial agents - among which academy, banks and ONGs, and, iii) technological & environmental actors - as entrepreneurs and niche innovation companies.



MLP in the Brazilian Perspective.

Source: The authors (2021) based on Geels (2002).

From the analysis of the Brazilian scenario, we sense that the groups coexist at the multiple levels of the MLP, exchanging views and influencing each other, while suffering pressure from the socio-technical landscape that represents aspects that are exogenous to the sector itself.

ISDRS Conference 2022
Sustainable development and courage: culture, art and human rights
Stockholm June 15-17

Partial pressure analysis of CO_2 (pCO_2) up- and downstream of a hydropower plant in Kattstrupeforsen, Sweden.

Introduction

The atmospheric concentration of carbon dioxide (CO_2) has increased by as much as 45% since the start of industrialization. Carbon dioxide plays a major role for the global climate and the CO_2 emission from inland waters is a major component in the global carbon cycle and is estimated to 1.9 PgC yr^{-1},(Human impact eq. to 7.8 PgC yr^{-1})[1]. All emission scenarios that limit global warming to 1.5°C require the use of large scale carbon capture and storage.

Study Aim

The aim of this study is to measure the partial pressure of CO_2 in the water up- and downstream of a hydropower plant. The guiding question in this context is whether the hydropower plant is able to capture the positive CO_2 fluxes and emissions provoked by turbulences in the water.

Material and Method

In addition to a preliminary literature review, the main focus was on methodological on-site work:

Materials:

- eosGP CO_2-sensor, datalogger for pCO_2 mapping
- Zerogas N_2 (0 ppm) and Ref. Gas CO_2 (1000 ppm)

Methodology:

- Built up of instrument supportive construction
- Sensor calibration
- Three-day check ups
  → Data download and sensor adjustments
- Spacial variation analysis
- Data analysis in Microsoft Excel

Figure 4: eosGP CO2, (Eosense Inc. Dartmouth, Canada)[4]

Figure 1: Map of Sweden[2]

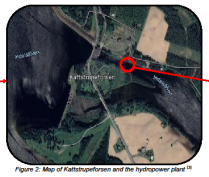


Figure 2: Map of Kattstrupeforsen and the hydropower plant [3]

Figure 3: Sensor supportive construction

Data analysis

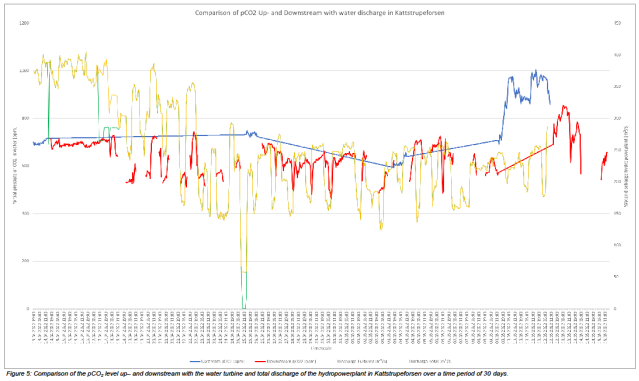

Figure 5: Comparison of the pCO_2 level up- and downstream with the water turbine and total discharge of the hydropowerplant in Kattstrupeforsen over a time period of 30 days.

Spacial variation analysis

Table1: Analysis of the sensor signals values in different spacial variations within the measuring period of the 6th of may in 2022 . The values in the timespans are average values from thiese periods

Time 06.05.2022	pCO2 [ppm]	Temperature [°C]	Spacial variation
9:40	600.27	11.07	Instrument mounted normally
10:50	71.79	19.60	First calibration with the zero gas
11:00	864.01	23.60	Second calibration with CO2 (1000 ppm)
11:15 - 12:00	584.28	9.17	Sensor 24 cm above bottom level
12:00 - 13:00	657.58	8.45	60cm further out, instrument fully submerged, free floating
13:10 - 14:50	634.58	8.78	130cm further out, instrument fully submerged 10cm into water, sensor immobilizely mounted
14:50	1561.77	6.29	Instrument placed 10 cm above the bottom, catches up bottom signal
15:00	636.09	8.61	
15:10	580.37	8.99	
15:20	610.85	8.54	

Discussion

The spacial variation proves that a variation of the rivers surface position has no influence on the pCO_2. The opposite effect showed a variation in the water depth due to the bottom signal of organic matter and the air signal caused by low water levels. When the water discharge of the power plant was low, the water level decreased, which resulted in no pCO_2 value being measured. This is due to a service maintenance of a turbine since 25th April. The sensor height was in most cases adjusted to the water level. If no pCO_2 value downstream is available, the sensor measured the air signal.

Conclusion

Since the pCO_2 is higher upstream than downstream, it can be concluded that the fluctuation of the water due to the turbines leads to an increased water-gas exchange and thus CO_2 could be stored in the hydropower plant.

Measuring Sustainable Energy Transition: A comparison of indicator sets

Éva Kármán-Tamus[1], Dr. Tamás Pálvölgyi[1], Dr. Tekla Szép[2]

[1]Budapest University of Technology and Economics, Faculty of Economic and Social Sciences, Department of Environmental Economics and Sustainability, Budapest, Hungary. [2]University of Miskolc, Faculty of Economics, Institute of World and Regional Economics, Miskolc, Hungary

Abstract

Sustainable energy transition is a key element of circular economy, social welfare and justice. The recent global energy crises brought on by COVID-19 also highlighted the importance of decarbonisation and the necessity of shifting energy sources from fossil fuels towards renewable energy. Seeing the existing states and the trends based on changes is necessary for the process of decision-making, and indicator sets are a widely used tool to communicate various issues to policy makers. There are multiple indicator sets in connection with sustainability and energy, all assessing the issue with a different perspective and focus.

In our previous studies, we built a comprehensive indicator set and compiled a composite indicator for measuring the performance of the European Union Member States in the field of sustainable energy transition. Firstly, we developed representative indicators covering the three dimensions of sustainability (i.e. economic and development-related dimension, human and social dimension, and natural resource-related and environmental dimension), called Sustainable Energy Transition (SET) indicators. After multiple steps of data testing, we used normalization and weighting methods to calculate the composite indicator.

The goal of this study is to compare the Sustainable Energy Transition composite index and additional sustainability indicators, for example the Human Development Index (HDI), which provides an indication of a country's human well-being or the IEA's Energy Development Index (EDI), which focuses on a country's transition to the use of modern fuels. Our preliminary results suggest that interrelations between SET indicators and HDI show typical spatial distribution, mainly driven by the country's primary energy mix and differences in energy policies.

We attribute great importance to apply science-based results in policy making, therefore our research intends to assist policymakers in the sustainable development of national energy policies. It becomes clear that the global energy security, economic geography of globalization, the economics of climate change and climate policy are closely related, which means that we should concentrate not only on energy transition but we should raise the attention to the importance of the sustainable energy transition. Because of this, we developed our indicator set keeping the sustainable development goals in mind. Our study especially relates to SDG7 and SDG13, which may serve as a basis to achieve affordable and clean energy and to combat global climate change.

Abstract

The main purpose of this paper is to explore how public authorities can promote renewable energy tender participation of potential suppliers. Currently, public authorities struggle to attract more participants to tenders and thus to achieve lower prices and better quality of goods and services and to reach sustainability goals. By using arguments from the public interest theory of regulation and transaction cost economic theory we investigate how evaluation criteria, type of tendering procedure, submitted value of the tender, and common procurement vocabulary affect the number of participants in public tenders and, thus, contribute to the openness and competition in the bidding process of renewable tenders. For public agencies, the obtained results demonstrate the importance of paying attention to tendering procedures and types of goods and services in relation to the number of participants in public tenders. Public agencies, therefore, generate a twofold impact on promoting sustainable goals – one via different types of the tendering procedure, and the second via the goods and services acquired.

Keywords: Public procurement, Sustainability, Renewable energy, Policies

1. Introduction

Climate change, the COVID-19 pandemic, migration, inequality, and growing unemployment are challenges that we are faced with nowadays and to a large degree connected with consumption patterns. The government plays an important role in managing these patterns, being an important and influential customer (Halonen, 2021; Rosell, 2021). For example, worldwide public procurement accounts for around 14% of the global GDP and EU public procurement accounts for around € 1.8 trillion per year (Cinti, 2020). Being an important customer, the government in the form of public authorities has the potential to use its power to boost sustainable development. Also, this potential seems large and essential, scientific insights, in general, are scarce on what policies and strategies can help public authorities to address current global and local challenges.

Public procurement policies regulating the purchase of goods and services have been benefiting societies through ensuring access to available resources and reliable energy services, improving energy efficiency, increased innovation, and efficient resource use. During the last decade, there has been a growing recognition of the importance of public procurement legislation to promote sustainable development goals (Lundberg and Marklund, 2018; Pouikli, 2021). Public procurement policies can facilitate the aforementioned goals and policies through the increasing number of bidders per tender from one side and challenging public authorities to find innovative solutions to promote the sustainable behaviour of tender companies (Jääskeläinen and Tukiainen, 2019). However, these policies that aim at changing the behaviour of companies willing to participate in public procurement tenders remain a challenge for public authorities. Moreover, it is highlighted that public procurement is characterized by a low rate of competition that negatively affects its efficiency (Nemec et al., 2020). From a theoretical perspective, there is currently a lack of knowledge about key constructs on how public procurement policies can be developed and what type of information is required by tenderers to facilitate a tendering process. Therefore, this paper seeks to answer the following research question: *what are the key types of factors that affect the number of participants in public tenders and, thus, contribute to the openness and competition in the bidding process of renewable tenders?*

Particularly, since the area of public procurement is not well theorized (Flynn and Davis, 2014), we use arguments from the key public procurement theories including the public interest theory of regulation (Stigler, 1971) and transaction cost economic theory (Williamson, 1993) we formulated key hypotheses to investigate how evaluation criteria (based on price only, on cost only, or on best price-quality ratio), type of tendering procedure (open, simplified, or direct award), submitted value of the tender, and common procurement vocabulary (CPV) affect the number of participants in public tenders and, thus, contribute to the openness and competition in the bidding process of renewable tenders. We collected public procurement tenders' data in Sweden from a database, Visma Opic which resulted in the final sample of 187 companies. Two different regression methods of Poisson and negative binomial were applied to test the formulated hypotheses.

In contrast to previous literature, we found that the evaluation mechanism has no significant impact on the number of tenderers. However, the type of procedure 'simplified' shows a positive significant effect. Moreover, CPV in terms of 'electricity' and 'architectural services' also has a significant effect on the number of participants in tenders which contributes to the openness and competition in the bidding process of renewable tenders. Therefore, this paper provides important knowledge on a highly debated and complex topic in predicting the number of potential bidders in the public procurement process (Ballesteros-Pérez et al., 2016; Jääskeläinen and Tukiainen, 2019) by highlighting the importance of specific factors, including a tendering process and tender characteristics.

In the next section, we present key literature and factors that according to previous studies can affect the number of participants in public tenders. Further, we describe how we collected and analyzed the available data. In the next sections, we present the results and conclusions of the present study.

2. Literature review

Public procurement is a complex phenomenon with several stakeholders and contradicting demands, including as a result the best economic outcome, yet efficiency goals compete with political goals and environmental issues (Rokkan and Haugland, 2021). Theoretical application in public procurement research is highlighted as low and the area of public procurement is under-theorized (Flynn and Davis, 2014). In our study, we use arguments from the public interest theory of regulations (Stigler, 1971) and transaction cost economic theory (Williamson, 1993). In general, the public interest theory of regulations states that regulation is formulated in a way to protect and benefit public at large to overcome unbalanced market results (Hantke-Domas, 2003). According to this theory, public agencies have to provide equal treatment of suppliers and strict procedures with high transparency. Although the public interest theory of regulations does not explicitly explain participating in a tender, procurers are assumed to follow public interest theory in order to develop their regulations to not violate public trust and encourage participation in the procurement system. While regulations are developed by public agencies to benefit public at large, at the same time these agencies should control and constantly work on the reduction of costs in tenders. According to transaction cost economic theory (Williamson, 1993), procurement strategy and transaction attributes should match in order to decrease transaction costs that occur due to economic exchange. Comprehensive accounting and reduction of such costs without sacrificing value should become one of the most important elements in public process efficiency and optimization (Williams, 2014; Petersen et al., 2019). In our case, we can hypothesize that when the number of tenderers increases there is more room for negotiation and a higher probability that prices, including transaction costs of tenders, will decrease.

To attract tenderers in the auctions, public agencies should consider certain factors that affect the tenderers decision to bid and competitiveness in the tendering process. For example, it is highlighted that the decision to bid is based on the attractiveness of the tender and market situation (Leśniak and Radziejowska, 2017). In another study, it was established that job characteristics, the company strength, design quality, the project cash flow and rate of return are important factors influencing the decision to bid (Alsaedi et al., 2019). Another type of research demonstrates that estimated value of procurement, award price context and accuracy of cost estimation are also important in attracting tenderers to auctions (Fry et al., 2016; Hanák, 2016; García Rodríguez et al., 2019). Bidders experience is also shown as one of the most important factors that can affect competitiveness in tenders (Keung and Shen, 2017). While it is shown that there are different types of factors that can affect the decision to bid and competitiveness in public procurement context, this area requires more studies of historical data from past tenders to create a basis for further development of public procurement policies and strategies (Jaśkowski and Czarnigowska, 2019). In our study, we include two types of factors that were available from historical data: (i) factors that characterize a tendering process (evaluation criteria and type of tendering procedure) and (ii) tender characteristics (submitted value of the tender and CPV).

2.1 Evaluation criteria

It is of utmost importance that companies' participation in tenders and the tender assessment follows a transparent process on the basis of equal treatment, non-discrimination with particular attention to the principle of proportionality. General provisions for public procurement ask companies and procurers to ensure open access to all suppliers, and it prohibits design of procurements that excludes a group of suppliers (Sweden law of public procurement, 2016; Dotoli et al., 2020). Evaluation criteria are decisive for giving guidance to tender evaluation and for selecting the bidder having the highest score (Bergman and Lundberg, 2013; Chen, 2008; Mateus et al., 2010; Stilger et al., 2017). Evaluation criterion could be based on price only, on cost only, or on best price-quality ratio (European Commission, 2018). The first form is the most popular one in which the lowest price bid will be awarded a tender (Konkurrensverket, 2020). Cost evaluation means cost effectiveness which can be expanded to include life cycle costs. Petri and Olve (2014) discuss that investment calculations (such as life cycle cost analysis) which extend across both production and market and include entire life cycle are seldomly used compared to traditional product calculations. The best price-quality ratio (BPQR) is flexible, and it allows to consider environmental or social considerations together with quality in awarding a tender (European Commission, 2018; Preuss, 2011). The BPQR was formerly labelled as the most economically advantageous tender (MEAT). MEAT was used as a criterion instead of the lowest price bid. However, the new public procurement guideline specifies MEAT as the umbrella name for awarding a contract when price, costs, and BPQR are used in the assessment approach (Directive 2014/24/EU, European Commission, 2018; Konkurrensverket, 2019).

The price competition through awarding contracts to the lowest price bid has been the traditional evaluation criteria and is an effective approach limiting favoritism (Bulow and Klemperer, 1996; Yao and Tanaka, 2020). But, due to concerns about quality, and later by including environmental and societal criteria in public procurement (Sebastian et al., 2020), other approaches such as BPQR and life cycle costs analysis are increasingly used. The European Parliament and the council of the European Union formulated directives in 2014 to encourage procuring organizations to increase quality orientation in public procurement (Directive 2014/24/EU). The advisory board for the European Research Area asked for 2% budget of public procurement to be dedicated to innovation. The Europe 2020 flagship initiative "Innovation Union" is an example of dedication of public procurement to increase innovation to improve quality (Appelt and Galindo-Rueda, 2016). Whether choosing an alternative approach compared to the lowest price bid led to higher quality is still a matter of debate. Bergman and Lundberg (2013) argue that although the combination of quality and price is a suitable criterium for evaluating contracts, in situations where several potential suppliers can offer the same product the usage of lowest price bid is preferable. The level of the desired quality needs to be specifically mentioned otherwise high-quality bidders are more likely to withdraw from lowest price bid procurements (Yao and Tanaka, 2020). Although BPQR and cost evaluation are used to reduce the effect of lowest price in tenders by means of including other criteria to award a contract, the result of another study shows that there is a marginal greater risk for review compared to lowest price bid (Konkurrensverket, 2014). This marginal difference can be explained by a lower number of tenders with BPQR as evaluation criteria compared to lowest price bid. Hence, the decision whether

BPQR and cost evaluation in procurement are effective in increasing competition relative to lowest price is still an unsettled question. Therefore, the research hypotheses can be formulated as follows:

H1: The choice of evaluation criteria plays a significant role in increasing the number of participants in public tenders.

2.2 Type of tendering procedure

Further, we include in the research model such an important factor as a type of tendering procedure since public procurements have to follow these specific procedures prescribed by the legislation. While this factor is shown to be important in relation to competitiveness and openness of public tenders (Heijboer and Telgen, 2002; Tikkanen and Kaleva, 2011; Soudek and Skuhrovec, 2016), current literature is lacking studies that can guide public authorities in choosing the optimal tendering procedure that minimizes transaction costs and increases competitiveness. In relation to competitive tendering, it was recommended before choosing either more open or more restricted tender procedure, it is important to take into account the expected level of market competition, expected tendering costs and time that will be involved (Heijboer and Telgen, 2002). In empirical studies, it was shown that the open procedure was preferable than more restricted procedure when the value of the contract exceeded the EU threshold (Tikkanen and Kaleva, 2011). Another study has shown that an open procedure can reduce the final price of the tender and attract more competitors (Soudek and Skuhrovec, 2016). Yet, the choice of the tender procedure by relying only on the public procurement regulation without having a clear methodology on how this choice is related to the procurement process costs was criticized in another study (Carbonara et al., 2016). In general, if the tender is about the established threshold public authorities are obligated to announce tenders at the EU level. In another case when threshold is not reached, the tender is announced at the local level. Given the above, we hypothesize that:

H2: The choice of tendering procedure plays a significant role in increasing the number of participants in public tenders.

2.3 Submitted value of the tender

While in a regular auction, a seller wants to sell items to several tenderers with the highest possible price, public procurement has a reverse auction where a public agency as a single buyer wants to purchase items from several tenderers (Chen et al., 2005). Moreover, public agencies want to spend their financial resources as efficiently as possible and usually during the reverse auction prices decrease when the tenderers underbid each other. Therefore, tenders are awarded usually to the bids that bring the best value for money for the public agency.

From the point of view of the tenderer, the bid estimation strategy is crucial to ensure probability of winning tenders and, at the same time, economic efficiency of the tendering company (Hanák et al., 2021). When a tenderer decides to bid on a contract, a submitted value of the tender (an estimated value of a procurement that public agency is willing to pay for the performance of the public contract) can play a significant role

value of procurement has a direct impact on the number of tenderers in the public auction and a higher estimated value attracted more tenderers (Onur et al., 2012). In another study, it was found that there is a slight positive correlation between price difference of a tender (expected and awarded prices) and the number of submitted offers (Man et al., 2014). It was established that in the multicriteria bidding strategy of tenderers besides risks and attractiveness, cost-oriented pricing plays one of the main roles in the decision to participate in public tenders (Hanák et al., 2021). Therefore, the hypothesis can be formulated as follows:

H3: The submitted value of the tender plays a significant role in increasing the number of participants in public tenders.

2.4 Common procurement vocabulary

Transparency of public procurement is highlighted as one of the key issues to promote competitiveness and openness of the procurement process (Coviello and Mariniello, 2014; Lundberg and Bergman, 2017). To promote higher transparency and simplify the tendering process, governments make their procurement data accessible online on different platforms. It was shown, for example, that in countries with more transparent procurement systems, the probability of firms to engage in the bidding process is higher (Knack et al., 2017). In another study, it was also confirmed that the public accessibility of procurement data increases the likelihood of improved competitiveness and facilitates the entry of new tenderers (Duguay et al., 2020). However, while in general it is established that the transparency is important for public procurement competitiveness it is highlighted that future research should provide more detailed evidence on which types of transparency matter for openness and competitiveness of public procurement (Bauhr et al., 2019; 2020). In our study, we focus on CPV codes which is a classification system that standardizes contract type by product as one of the transparency types. We consider this vocabulary as one of the channels through which transparency contributes to better competition through improving business efficiency. Potential tenderers benefit from this vocabulary by saving time on information collection and analysis. Therefore, we expect that:

H4: Common procurement vocabulary plays a significant role in increasing the number of participants in public tenders

3. Methods

This section contains data collection, variables, and data analysis.

3.1 Data collection

We used public procurement databases in Sweden, and Tenders Electronic Daily (TED) to find tenders that were related to renewables. Dataset included tenders that had their closing date in the year 2020. The geographical focus was on Sweden. This consideration made it possible to cross check tenders between

as evaluation criteria, and 283 used price as the evaluation criteria. Then, we ruled out “cancelled” tenders, and the ones with unclear decision or unclear information about tenderers to focus only on successful tenders which have information about tenderers as well. In total, our sample contained 187 tenders.

3.2 Variables

"Submitted value of the tender" added as a continuous variable. Then, we created dummy variables from evaluation criteria, "type of procedure", "Main CPV" to add to the regression model. There were 22 different CPV codes and testing them showed that CPV codes belong to architectural services, and electricity are significant predictors in the regression model. These two CPVs are independent (in other words one tender submit to either of these CPVs), and as a result they were incorporated in two separate regression models. Table 1 explains variables and frequency of appearance in the dataset including the mean and max for tenderers count and Submitted value of the tender. Figure 1 shows the frequency of and descriptions of CPV codes as it appeared in the final dataset.

Table 1. *Variables definitions and references.*

Variable	Subgroup (Frequency)	Definition	Ref
Tenderers count	No subgroup (1-11 participants)	Number of participants in a tender	
Evaluation criteria	Price-Quality (55)	tender evaluation criteria: The Best Price Quality Ratio	EU public procurement directive 2014/24, Article 67
	Price (132)	tender evaluation criteria: lowest bid	EU public procurement directive 2014/24, Article 67
Type of procedure	Open (42)	Anyone may submit a full tender and there is no opportunity for negotiation	https://europa.eu/youreurope/business/selling-in-eu/public-contracts/public-tendering-rules/index_en.htm https://www.upphandlingsmyndigheten.se/inkopsprocessen/forbered-upphandling/valja-upphandlingsforfarande/
	Simplified (134)	Anyone may submit tenders and there is an opportunity to negotiate with the supplier	https://www.upphandlingsmyndigheten.se/inkopsprocessen/forbered-upphandling/valja-upphandlingsforfarande/
	Direct award (11)	Direct purchasing when the value of the procurement is below direct procurement limit, and under certain situations. EU:s general provision must be followed.	https://www.konkurrensverket.se/upphandling/lagar-och-regler/direktupphandling/ https://www.konkurrensverket.se/upphandling/lagar-och-regler/troskelvarden/
Main CPV	22 subgroups	Common procurement vocabulary for classification	https://www.upphandlingsmyndigheten.se/inkopsprocessen/forbered-upphandling/valja-upphandlingsforfarande/
Submitted value of the tender	No subgroup (17297 Kr. – 32077000 Kr.)	Estimated value of a procurement	https://data.europa.eu/euodp/repository/ec/dg-grow/mapps/TED_advanced_notes.pdf

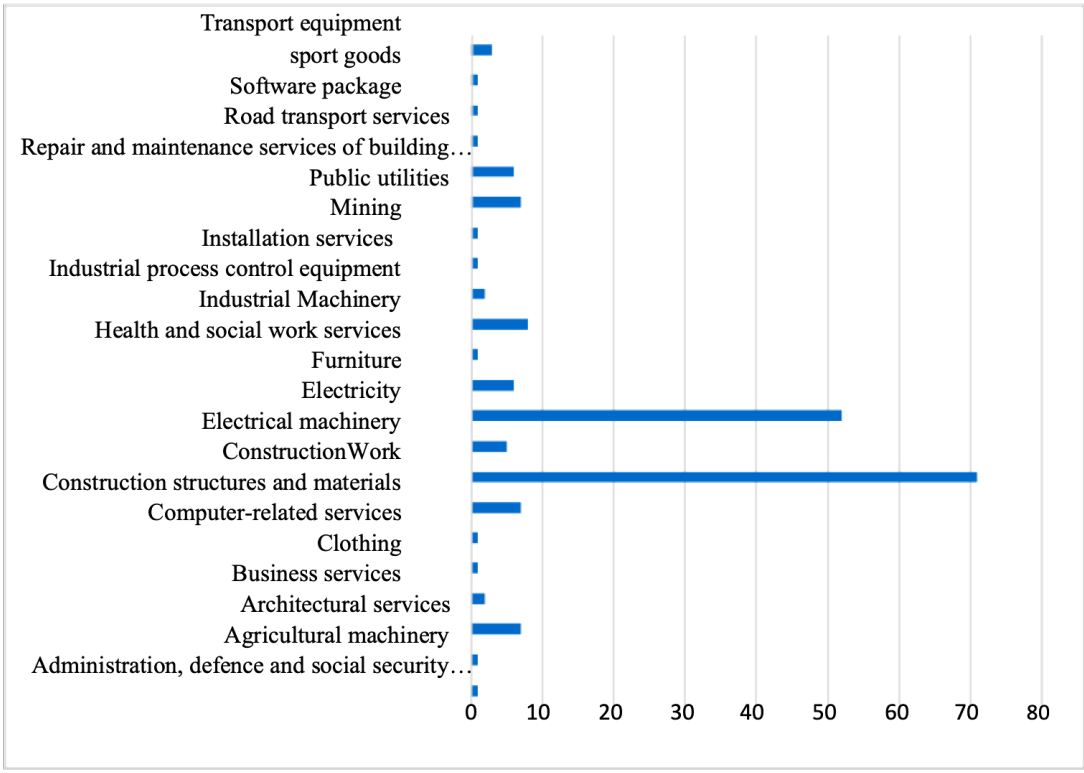

***Figure 1**. CPV codes.*

3.3 Data analysis

Boxplot and ggplot were among techniques we used to identify and remove extreme values, and outliers. We investigated the mean and variance differences among predictors to examine how big the difference between mean and variance are. The bigger the difference between mean and variance the better predictor variable. Evaluation criteria did not show that it is a good predictor variable while type of procedure showed better results. However, we took both to the regression model to see whether it impacts prediction results of the regression model.

The dependent variable of this model was to find what factors affect the number of participants in public tenders through testing four research hypotheses. Hence, we created a regression model, and used negative binomial regression model. This type of regression which is the more generalized form of Poisson regression is suitable for over dispersed data (Cameron and Trivedi, 2013). Testing the size of variance to the mean for the dependent variable revealed data dispersion and the usefulness of using this method over Poisson regression (Variance Tenderers count / Mean Tenders count = 2.282). We used R-programming for data analysis. We created factor models from “evaluation criteria” and “type of procedure”. “Price” subgroup was the reference group in evaluation criteria, and “direct award” subgroup was the reference group in “evaluation criteria”.

4. Results and discussions

The negative binomial regression models the log of the expected count as a function of the predictor variables. Table 2 and 3 shows parameter estimates using negative binomial regressions. The dependent (Response variable) is "Tenderers count" and beneath are predictor variables.

Table 2 shows that evaluation criteria: price-quality, and type of procedure: simplified, and main CPV: architectural services including intercept are significant predictors of tenderers count. The indicator variable shown as "type of procedure: simplified" is the expected difference in log count between this group and the reference group (type of procedure: direct award). The expected log count for "type of procedure: simplified" is 0.625 higher than the expected log count for "type of procedure: direct award". Also, for a one unit change in the "main CPV: architectural services" variable, the difference in the log of expected counts of the response variable is expected to change by 0.75, given the other predictor variables in the model are held constant. The negative binomial regression estimates when all variables in the model were evaluated at zero showed that the log of the expected count for "tenderers count" is 0.768.

Table 2. *Negative binomial regression parameter estimate results: Architectural services.*

Tenderers count	Estimate	Std. Error	z value	Pr(>|z|)	
(Intercept)	0.768	2.42E-01	3.166	0.00155	**
Evaluation criteria: Price-Quality	-0.0584	1.07E-01	-0.547	0.58468	
Type of procedure: open	0.325	2.72E-01	1.199	0.23072	
Type of procedure: simplified	0.625	2.46E-01	2.539	0.01111	*
Main CPV: Architectural services	0.753	2.32E-01	3.253	0.00114	**
Submitted value of the tender	-0.000	7.69E-09	-0.966	0.33416	

Significance codes: * p < .05, ** p < 0.01, *** p < 0.001
Number of observations = 187
2 x log-likelihood: -806.408
BIC: 843.0258

Table 3. *Negative binomial regression parameter estimate results: Electricity.*

Tenderers count	Estimate	Std. Error	z value	Pr(>|z|)	
(Intercept)	0.715	2.45E-01	2.916	0.00354	**
Evaluation criteria: Price-Quality	0.002	1.10E-01	0.022	0.98217	
Type of procedure: open	0.398	2.71E-01	1.469	0.14187	
Type of procedure: simplified	0.574	2.48E-01	2.311	0.02084	*
Main CPV: Electricity (solar panel and energies…)	0.250	1.08E-01	2.312	0.0208	*
Submitted value of the tender	0.000	7.79E-09	-0.483	0.62887	

Significance codes: * p < .05, ** p < 0.01, *** p < 0.001
Number of observations = 187
2 x log-likelihood: -810.87
BIC: 847.4881

Results of table 3 shows that "type of procedure: simplified" is about 0.574 higher than "type of procedure: direct award", and one unit change in "electricity CPV" will change the log of expected counts of "tenders count" by 0.25 unit. The negative binomial regression estimates when all variables in the model were evaluated at zero showed that the log of the expected count for "tenderers count" is 0.715 for tenders in electricity subgroup. We also did ANOVA tests to make sure to know whether subgroups are significant or the whole variable is significant. ANOVA test showed that "type of procedure" and "Main CPV" are significant predictors for "Tenders count" variable.

These two models can be simplified in the following equations. The log of the "tenderers count" can be predicted with a linear combination of "type of procedure" and "Main CPV" in architectural services" and "electricity":

Tenderers count = exp (Intercept + 1.05*Main CPV+0.67*Type of Procedure simplified) Main CPV: Architectural services

Tenderers count = exp (Intercept + 0.341*Main CPV + 0.59*Type of Procedure simplified)
Main CPV: Electricity (solar panel and energies…)

Table 4. *Results of hypothesis test.*

	Hypothesis	Supported
H1	The choice of evaluation criteria plays a significant role in increasing the number of participants in public tenders.	No
H2	The choice of tendering procedure plays a significant role in increasing the number of participants in public tenders.	Yes
H3	Submitted value of the tender plays a significant role in increasing the number of participants in public tenders.	No
H4	Common procurement vocabulary plays a significant role in increasing the number of participants in public tenders.	Yes

Table 4 shows that hypothesis 1 which is about the impact of evaluation criteria is insignificant. Although a previous study (Sebastian et al., 2020) suggest to use BPQR, but our study did not find a significant effect of either of these variables. One explanation could be that number of tenders with BPQR as criteria were much lower than the reference group (price-quality: 55 tenders, price: 132 tenders). We suggest future research to consider samples with higher number of tenders with BPQR as evaluation criteria.

Hypothesis 2 was supported, and it showed the that simplified procedure type is a significant predictor compared to direct award. But type of procedure: open could not show significant difference compared to type of procedure: direct award in predicting cumber of tenderers. It is worth to mention that we tested to exclude CPV codes from the regression equations which gave marginal significance (p -value < 0.1) to tender type: open in comparison to reference group direct award. However, tender type: simplified was still significant and stronger which showed the higher prediction power of this type of procedure in determining the count of tenderers. As stated in the literature review, previous studies mention the importance of choosing the optimal procedure type (Heijboer and Telgen, 2002; Tikkanen and Kaleva, 2011; Soudek and Skuhrovec, 2016). Although Tikkanen and Kaleva (2011) mentioned the importance of type of procedure: open, but our study did not find support for that. It could be argued that type of procedure: simplified is an extension of type of procedure: open with the privilege of negotiation which might make this procure type more suitable for SMEs.

We did not find significant effect of submitted value of the tender on number of tenderers, and hypothesis 3 is not supported. In this regard, our results are rejecting the findings of a previous study (Onur et al., 2012) on the role of submitted value of a tender. The reason to this might be the high dispersion of values (mean: 4.96E+06, variance: 4.7E+13). Therefore, we suggest future research to consider this variable as a categorical variable rather than a continuous variable.

Common procurement vocabulary plays a significant role in number of tenderers (H4). There were two CPV codes among 22 CPVs of renewables which showed significant effect, architectural services, and

these CPV codes attract many tenderers. For instance, one tender attracted 57 tenderers, and 10 of which were winners. Also, electricity tenders appeared quite often in renewable tenders, and it attracted several tenderers. Thus, current study support findings of previous study on importance of transparent procurements (Coviello and Mariniello, 2014; Lundberg and Bergman, 2017), and introduces electricity and architectural services as two popular categories for tenderers in renewable energies.

4.1 Extended model

This part is for further research, and we appreciate feedback on that. We also run different models with further variables to investigate whether prediction of the model improves. We used Bayesian information criterion (BIC) for scoring and selecting a model with lowest score. We created a new dependent variable which is the sum of winners and tenderers called WinnersTendersCount. This new variable will give us more tenders since 34 tenders were excluded from dataset since the information for tenders were missing while information for winners existed. This could be because of data entry mistakes in the databases and tenders were ignored. Theoretical justification for this variable is that variables are part of tenderers and those predictors variables that predict number of tenders can predict number of winners. In other words, tenderers turn to winners and these predictors can be considered as predictors of winners. Then, we created few other predictor variables. One of them was to consider the logarithmic transform of the submitted value of tender to reduce the variation of this predictor variable. Furthermore, we computed another categorical variable which shows the type of procurer. We found that there are different categories of procurers; university, limited companies (Aktiebolag in Swedish), government, and municipalities. Results showed that logarithmic transformation of the "submitted value of a tender", and count of winning by a firm, "type of procedure: direct award" can predict the dependent variable which is the number of winners and tenders. This model showed lower BIC compared to main results of the paper.

5. Conclusions

With the research question of what are the key types of factors that affect the number of participants in public tenders, this paper goal was to contribute to the openness and competition in the bidding process of renewable tenders. Achieving this goal help public authorities to promote renewable energy tender participation among potential supplier and reach sustainability goals.

The research question was answered with help of formulating four hypotheses. Two hypotheses related to the impact of tendering process and common procurement vocabulary codes on number of tenderers were supported. Type of procedure: open and CPV codes of architectural services, and electricity showed significant results compared to their reference groups. While two other hypotheses related to the impact of tender evaluation criteria and submitted value of tender became insignificant. The regression models using significant variables are created for consideration of public procurers, policymakers, and SMEs. We have outlined several avenues for further research in the discussion part of this paper.

Abstract

A Life Cycle Assessment (LCA) of unitized regenerative fuel cell (URFC) system with polymeric electrolyte membrane (PEM) applicable in residential buildings is carried out to evaluate the energy and environmental performances of this emerging energy storage technology. The individual components of the URFC system (catalyst, stack, balance of plate, storage tank, electric and electronic auxiliary devices) were modelled using Simapro software. The scope of analysis is cradle-to-grave, with a functional unit of 1 kWh of electricity produced by the URFC system in 10 years. The life cycle inventory of the study includes both primary and secondary data. In particular, primary data was collected from laboratory experiments conducted within the "ELETTRORIGENERA" project (PO FESR SICILIA 2014-2020 AVVISO 1.1.5 - PROGETTO ELETTRORIGENERA N. 08ME2899200216). Instead, secondary data, such as peer-reviewed studies and commercial databases, are used when primary data are unavailable. The potential impacts are evaluated using Cumulative Energy Demand (CED) and CML-IA baseline assessment methods. The results showed that 1 kWh of electricity produced by the URFC system could emit about 0.263 kg $CO_{2\,eq}$ in global warming potential and 15 MJ of cumulative primary energy. The operation phase is responsible for more than 65% of all impact categories, except for photochemical oxidation and acidification potentials, in which the highest impacts are linked to the manufacturing phase. In addition, the analysis identified that catalysts generate the most significant impacts in URFC system manufacturing. On the contrary, although end-of-life treatments generate negligible impacts, recycling part of metals and catalysts to avoid the production of virgin materials could reduce the impacts by at least 38%. Further, these results could be used in future studies to evaluate the impacts generated by different end-of-life and control strategies of the URFC system and their effects on the hydrogen technology's performance and compare alternative energy storage technologies.

Keywords: Life cycle assessment (LCA), PEM, URFC, hydrogen technology, end-of-life

1. Introduction

In 2020, energy production and its use accounted for over 75% of the European carbon dioxide (CO_2) emissions (Eurostat, 2021). Therefore, decarbonizing the energy system is one of the primary keys for achieving carbon neutrality by 2050. Within the new Green Deal (European Commission, 2019), European Commission (EC) proposed a series of indications to reduce emissions and external energy dependencies. One of these proposals refers to installing renewable energy systems (RES). However, their wide application in the years was restrained due to their intermittent energy production, which could generate a mismatch between offer and demand, causing, e.g., electric grid instability in the case of photovoltaic panels (PV) and wind farms. To resolve this issue, policymakers and industries are pushed toward developing and investigating high-efficiency energy storage systems coupled with renewable sources for increasing self-consume (Wang et al., 2016).

Among the different proposed energy storage systems, the Proton Exchange Membrane Unitized Regenerative Fuel Cell (PEM-URFC) is a promising energy storage technology that can produce clean energy for different sectors, from building to industry and mobility sectors. Indeed, this electrochemical device could work both in fuel cell (FC-mode) and electrolysis (EL-mode) modes producing, from water and electric energy, hydrogen, oxygen and thermal energy convertible into electric energy and water vapour when required (Saeed & Warkozek, 2015).

Despite this potential advantage during the operation phase, the manufacturing and disposal of such PEM-URFC systems may be quite energy and resources consuming (as for their technological predecessors) due to manufacturing processes and raw materials used that could overlap the sustainability benefits of the technologies (Stropnik et al., 2019). For that reason, the environmental sustainability of this energy storage technology has to be evaluated, from raw materials extraction to disposal, including the manufacturing and operation phases.

In this context, the Life Cycle Assessment (LCA) method (ISO, 2020a, 2020b) could be applied to identify the main hotspots during the whole life cycle of an energy system or compare different technology management strategies. Indeed, this method can capture the complexity and interdependencies of technologies providing a comprehensive and objective analysis useful to address the environmental sustainability of systems and identify the potential impacts/benefits achieved during each life cycle phase. Its usefulness has been amply demonstrated by numerous LCA studies conducted on fuel cells and electrolyzers. Despite this, the energy and environmental sustainability of the life cycle of URFC systems has not been extensively evaluated. Indeed, based on the authors' knowledge, the research on PEM-URFC systems is still limited to the economic analysis of components and energy evaluation of their efficiency during operation (Gabbasa et al., 2014; Paul & Andrews, 2017), and only Mendecka et al. (2020) applied the LCA method to a solar-based poly generation system, accounting for a URFC as part of an off-grid system for non-residential buildings.

This preliminary study evaluates the potential energy and environmental performance of a small URFC system installable in residential buildings to increase knowledge of energy storage technologies. The proposed case

FESR SICILIA 2014-2020 AVVISO 1.1.5 - PROGETTO ELETTRORIGENERA N. 08ME2899200216). The LCA method is applied following a cradle to grave approach.

2. Material and Methods

2.1. Case study description

The proposed case study focuses on a PEM-URFC system characterized by a power of 1 kW and 3 kW, respectively, for FC-mode and EL-mode. The system is designed to work with electricity produced by PV panels mountable on the roof of residential buildings. The technology consists of: i) stack, ii) balance-of-power (BoP), and iii) storage of hydrogen. In particular, the stack is the core of the URFC system, which produces and reconverts the hydrogen fuel thanks to the bifunctional cells. Instead, the BoP is designed to: collect produced water, maintain the thermal balance, and produce regulated power. Generally, the BoP for supporting the PEM-URFC stack includes the cabinet, cables and electronic control units (Mendecka et al., 2020). Overall, the URFC during the use phase in EL-mode can produce hydrogen, oxygen and thermal energy. The hydrogen and oxygen are compressed and stored in tanks of polymer liner reinforced with composite material, while the heat is accounted as waste and purged in the environment. Instead, during FC-mode, URFC produces electricity and water vapour. The electricity could be directly used by end-users, while water vapour could be condensed and reused in EL-mode. Since URFC systems have not reached a mature development, the maximum lifetime of the component is not yet clearly established (Gabbasa et al., 2014; Mendecka et al., 2020). However, for this case study, a lifetime of 10 years is estimated (Mori et al., 2014), considering the average use of 4 hours per day in EL-mode and 4 hours per day in FC-mode. During tests conducted on existing URFC stacks, the efficiency for EL-mode and FC-mode respectively resulted in 0.8 and 0.5. Based on that, the URFC may produce 15,705 kWh of electric energy. The operation characteristics of the URFC system are reported in Table 1. Further information on the assumption made for estimating the energy and water consumption during operation is reported in section 2.3.

Table 1. *Summary of the operation characteristics of the URFC*

Parameters	EL mode	FC mode
Operating time, hours[1]	15,000	15,000
Efficiency[2]	0.80	0.50
Nominal stack voltage, V[2]	1.65	0.60
Nominal current density, A/cm2[2]	0.60	0.50
Nominal URFC power, kW[2]	3.00	1.00

(to be continued)

Table 1 *(continued)*

Parameters	EL mode	FC mode
Operating temperature, °C[(2)]	70	70
Operating pressure of H_2, bar[(2)]	0	15
Operating pressure of O_2, bar[(2)]	0	1
Electric energy consumed, kWh[(3)]	42,832	0
Electric energy from PV, kWh[(3)]	49,109	0
Water consumed | recovered, l[(3)]	9,158	8,395
H_2 produced | consumed, kWh[(3)]	34,265	0
H_2 produced | consumed, kg[(3)]	1,028	942

2.2. Goal and scope

The LCA method is applied according to the ISO 14040-44:2020 (ISO, 2020a, 2020b) using Simapro software (PRé Sustainability, 2022). The goals of this study are:

- to evaluate the energy and environmental performances of the life cycle of the PEM-URFC system;
- to identify the components or processes responsible for the highest environmental load.

The functional unit (FU) selected for the analysis is represented by 1 kWh of electric energy produced by the URFC in FC-mode in 10 years. No multifunctionality is accounted for in the URFC system for lack of information on the thermal energy produced during the FC-mode and accounted as waste.

The system boundaries are defined following a cradle-to-grave approach, including the processes connected to raw material extraction, components manufacturing, operation of the URFC system and its end-of-life. While, impacts of intermediate transport, installation and maintenance are excluded from the analysis due to a lack of information. Furthermore, the effects of cell degradation, which are supposed to be 1% every 1,000 cycles - resulting from preliminary tests on the bifunctional cell - are excluded from the model.

For the Life Cycle Impact Assessment (LCIA) phase, the CML-IA baseline method (CML - Department of Industrial Ecology, 2016) is applied. According to the guide for LCA of hydrogen technologies (Masoni & Zamagni, 2011), the following impact categories are chosen to be included: abiotic depletion (ADP), acidification potential (AP), global warming potential (GWP), eutrophication potential (EP), and photochemical oxidation formation (POF). Furthermore, the Cumulative Energy Demand (CED) (Frischknecht et al., 2015) is also assessed, dividing the six indicators into renewable and no-renewable contributions.

2.3. Life cycle inventory

The foreground life cycle inventory of the URFC is modelled using both primary and secondary data.
Primary data are collected from the system's preliminary design and laboratory experiments within the ELETTRORIGENERA project. Secondary data are used when primary data are unavailable, collecting them from literature studies and commercial databases. The energy and environmental datasets are selected from

Ecoinvent 3.8 (Wernet et al., 2016). A depth description of inventory data is reported below, divided into URFC life cycle phases: i) manufacturing, ii) operation and iii) end-of-life.

2.3.1. Manufacturing phase

Concerning the manufacturing processes of the PEM-URFC stack, the data are collected through interviews of ELETTRORIGENERA projects' partners and refer to weight of materials and number of components. In particular, the PEM-URFC stack includes 30 bifunctional cells with an active electrode area of 100 cm^2, fixed between two gaskets and endplates with ties and rods. Each bifunctional cell consists of: i) a membrane electrode assembly (MEA), ii) a bipolar plate, iii) two frames, and iv) two gaskets whit hole (polytetrafluoroethylene - PTFE). A detailed list of components and primary materials used is reported in Table 2.

Foreground data for BoP and storage are estimated according to Lotrič et al. (2020) and Mendecka et al. (2020). Since the data of selected literature case studies correspond to different power sizes, the mass for BoP and storage are estimated by scaling down the mass of each resource to match the power sizes of the case study. This calculation is performed following the approach used for biogas plants by Fusi et al. (2016) by modifying the equation (Eq. 1) in order to estimate the mass of materials instead of environmental impacts as follows:

$$m_k = (P_{URFC} / P_{ref})^{0.6} \cdot m_{k,ref} \qquad \text{Eq. 1}$$

where is the mass of k^{th} materials of system object of study and reference (*ref*) system, P is the power of URFC system in EL-mode and that of the reference case study (*ref*), 0.6 is the scaling factor used according to Fusi et al. (2016).

The inventory data are summarised in Table 2, specifying the sources of data, the availability of manufacturing datasets and the amounts of materials for FU. However, the inventory data of some materials of the URFC stack (i.e., Nafion, PTFE and Iridium and Ruthenium oxide) are missing in the Ecoinvent database. For that cases, the amounts of energy and resources used for manufacturing are estimated according to previous literature studies on PEM-fuel cells and electrolyzers (Evangelisti et al., 2017; Simons & Bauer, 2015; Stropnik et al., 2019b; Zhang et al., 2015), except for $IrRuO_2$. For this latter case, having no LCI data available in the literature, impacts are assumed to equal palladium, general mining with ruthenium and other platinum group metals (Mori & Štern, 2016; Snowden-Swan et al., 2016).

Table 2. *Materials for the URFC manufacturing for FU (1 kWh of electric energy produced by the URFC in FC-mode in 10 years)*

Intermediate products	Materials	Dataset	Units	Value

[c] manufacturing process assumed as PET,
[d] manufacturing process assumed by (Simon and Bauer, 2015)

2.3.2. Operation phase

The use phase of URFC includes the consumption of electric energy from PV and deionized water. For calculating these values, energy, hydrogen, oxygen and water flows are calculated using the energy and chemical performances (i.e., efficiency, voltage and current density - Table 1)[1] of the URFC stack in a simplified model developed to design a renewable fuel cell[2] (Saeed & Warkozek, 2015). While the energy consumed during compression of hydrogen in storage is calculated through the model of Saeed
Warkozek (2015), considering the operating pressure in electrolyzer (1 bar) and that in fuel cell (15 bar) modes. Then, the electric energy provided by the PV is the sum of the electric energy required by electrolysis and compression processes.

Instead, the final net water required in 10 years by URFC results in 763 kg. This value is calculated by subtracting the water vapour produced in FC-mode from that required in EL-mode. It is assumed that the water vapour may be condensed using, e.g., a passive system and, after purification, reused in EL-mode. This system may recover about 90% of the water consumable in EL-mode. The estimation is in line with the ELETTRORIGENERA project's partner consideration.

2.3.3. End-of-life phase

For the end-of-life phase, a range between 88% to 96% of metals are assumed to be recycled, according to Lotrič et al. (2021) and Mendecka et al. (2020). Full disposal has been assumed regarding other materials, i.e. Nafion, PTFE, and metals' remaining parts. They are treated as inert materials in landfills.

Concerning the electrocatalyst layers, the recycle treatment is modelled according to Duclos et al. (2017) and Lotrič et al. (2021), in which a hydrometallurgical process is used to recycle 76% of Pt from the MEA. Instead, the plastics are put in municipal incineration plants for energy recovery.

The datasets on the treatment of waste cables and electronic scraps from the control unit reported in Ecoinvent 3.8 are used to model the end-of-life of cables and auxiliary components.

In addition, all recycled materials are modelled as avoided energy and environmental impacts linked to the avoided virgin materials production. Thus, they are accounted for as "credit" in the results section to show their potential energy and environmental benefits.

[1]During laboratory experiments, the ELETTRORIGENERA project's partners were able to measure the efficiency, voltage, current density of URFC stack. These data are used into this study to calculate the in and out flows of hydrogen and water.

[2]The renewable fuel cell represents the Discrete Regenerative Fuel Cell (DRFC), the predecessor of the URFC technology, in which an electrolyzer and a fuel cell are separate components of the same system.

3. Results and Discussion

The life cycle impact assessment (LCIA) is presented in Table 3. In particular, the first column of the table shows the system's impacts without energy and environmental credits, while the second one shows potential impacts taking into account the credits. All values are expressed per FU.

In the first case, the URFC system could emit for FU about 2.76 x10^{-5} kg Sb_{eq} in abiotic depletion (ADPe), 3.49 x10^{-3} kg $SO_{2\,eq}$ in acidification (AP), 0.263 kg $CO_{2\,eq}$ in global warming potential (GWP), 8.02 x10^{-4} kg $PO_4^{3-}{}_{eq}$ in eutrophication (NP) and 1.56x10^{-4} kg $C_2H_{4\,eq}$ in photochemical oxidation (POFP) categories. Focusing on CED, the URFC could consume about 15 MJ of cumulative primary energy to provide 1 kWh of electricity to end-users, of which renewable energy sources (e.g., solar, biomass, and others) contribute 74%.

Table 3. *Energy and environmental impacts of 1 kWh of electricity supplied by the URFC system*

Impact categories	Unit	Total		Variation [%]
		without credit	with credit	
ADPe	kg Sb_{eq}	2.76E-05	2.64E-05	-4.3%
AP	kg $SO_{2\,eq}$	3.49E-03	2.13E-03	-38.9%
GWP	kg $CO_{2\,eq}$	2.63E-01	2.38E-01	-9.6%
NP	kg $PO_4^{3-}{}_{eq}$	8.02E-04	6.72E-04	-16.2%
POFP	kg $C_2H_{4\,eq}$	1.56E-04	1.05E-04	-32.9%
CED_{nr}	MJ	3.63E+00	3.26E+00	-10.2%
CED_r	MJ	1.16E+01	1.16E+01	-0.1%

The main environmental impact contribution (40% in AP to 99.5% in CED_r) in the URFC system comes from its operation phase (Figure 1). Instead, the manufacturing phase contributes from 0.47% (CED_r) to 59.34% (AP) and 52.30% (POFP) and end-of-life treatment for less than 2.07% (CED_{nr}).

Focusing on impacts with credits, it is possible to observe that recycling materials such as platinum, titanium and other metals could reduce the energy and environmental results of the URFC system. The highest variation is generated in the AP (-38.9%), followed by POFP, in which the impact is reduced by 32.9%. Instead, for the other impacts categories, the results decrease from 0.1% (CED_r) to 10.2% (CED_{nr}).

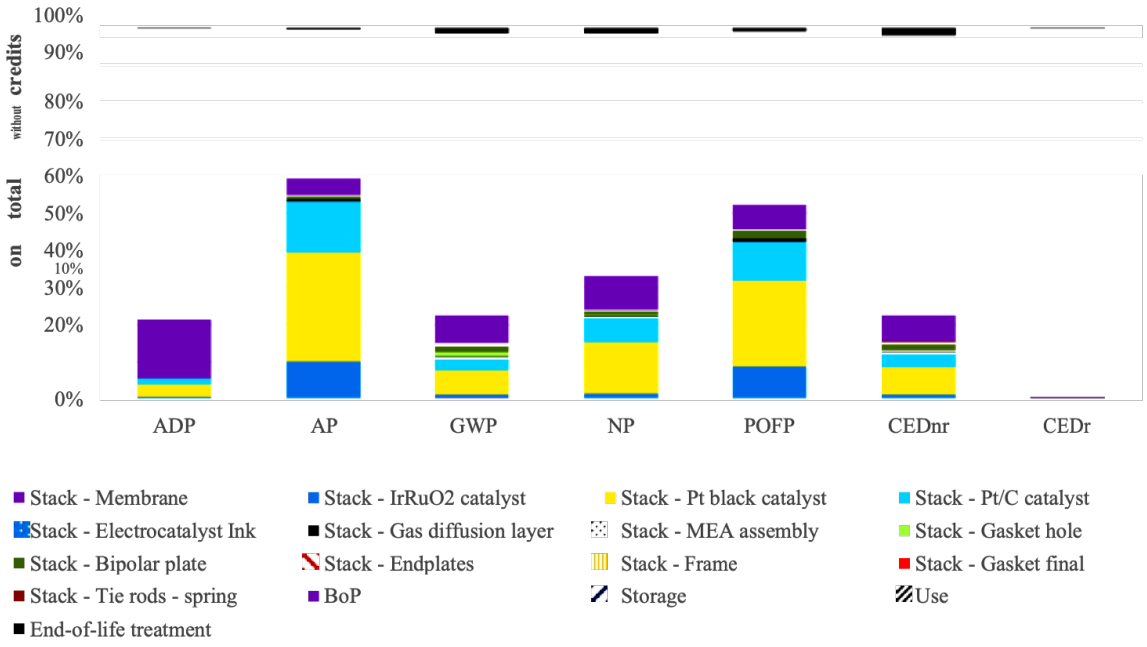

Figure 1. *Energy and environmental hotspots of the URFC system*

Regarding the URFC system manufacturing, stack production contributes from 25.82% (ADP) to 92.06% (AP), and it represents the most impactful component in all categories, except for ADP and CEDr, in which BoP is the main contributor. On the contrary, the lowest impact in URFC system manufacturing is related to plastic tanks contributing less than 1.80% in all environmental categories.

Concerning the URFC stack, its impacts are shared amongst these components: 62-97% coated catalyzed membrane (CCM) production (catalyst, membrane and ink preparation), 0.43-4.77% gas diffusion layer (GDL) production, 1.33-23.89% bipolar plates, and the last 0.98–11.50% represents the production of endplates, tie and rods, frames and gaskets. The catalysts manufacturing dominates the AP and ADP impacts of the CCM production for 96.85% and 95.00%. The leading reason for the high AP of catalysts is the sulphur dioxide emitted in the air during the extraction of the platinum metal groups (platinum and palladium) and their refinement at the site (Mendecka et al., 2020). While, the substantial contribution of catalyst production in ADP impact is caused by elements directly used in processes and those generally mined with them (e.g., gold, tellurium, nickel) (Snowden-Swan et al., 2016). Instead, the primary contributor to the NP impact of the stack is the phosphate water emission in the air that, as indicated in Mendecka et al. (2020), could be associated with the treatment of sulfidic tailing and spoil from mining. Bipolar plate production represents significant, although minor compared to the catalyst, environmental impact sources in GWP and CED categories. The primary contributor to bipolar plate production is heat, electricity and relative carbon dioxide emissions in the air.

Instead, the BoP production contributes from 7.93% (AP) to 74.19% (ADP) of the URFC system manufacturing, dominating the ADP and CED_r impact categories. This result is due to the production of the

Concerning the operation phase of URFC, the electricity provided by PV is responsible for more than 99% of each energy and environmental impact accounted for in this study. On the contrary, the water reintegrated for FU is about 0.05 kg, contributing to less than 0.01% of each impact category.

It should be highlighted that the preliminary study here presented is characterized by limits that could affect results. Most of them are connected to gaps in the literature and commercial databases, such as the missing: of reliable life cycle inventory for some materials production; of reliable information on energy and chemical performances of the URFC in an intermittent context for an extended period; of a model to estimate the effects of bifunctional cells degradation on resources; and of energy consumed for maintenance. These data need to be analyzed in depth via uncertainty analyses to observe the potential variations in model impacts in future studies.

In addition, the energy and environmental impacts of the operation phase could be affected by several factors, such as the operation lifetime or the technology used for electric supply. Indeed, although the electric energy source used in this study is renewable, the selected Italian renewable electricity generation from the PV dataset includes the manufacturing technology, which strongly affects the energy and environmental results of the URFC system. Indeed, if a wind turbine with a power size >1MW is used instead of 3kW PV panels mounted on building roofs, the impacts could be reduced from 32% in AP to 69% in ADP. On the contrary, using electric energy produced by geothermal plants could increase the CED by about 75%.

4. Conclusions

This study proposes a preliminary LCA study on a PEM-URFC system, from manufacturing to end-of-life. Primary data combined with secondary data were used to model the energy and environmental impacts of the life cycle of the URFC system. The paper aims to evaluate the energy and environmental impacts of 1 kWh of electricity produced by the URFC system in fuel cell mode and identifies which components could generate the most significant environmental load.

The analysis showed that the highest potential environmental impacts are associated with the operation phase, which contribution ranges from 40% to 99.5% (respectively for AP and CED_r), followed by the manufacturing phase from 0.47 to 59.34% (respectively for CED_r and AP), and end-of-life treatment for less than 2.07% URFC system impacts. The preliminary analysis of the potential reuse of metals and catalyst shows that by avoiding virgin material, production would decrease from 0.1 to 38.9% (respectively for CED_r and AP).

In addition, the catalysts' materials represent the resources that generate the most significant impacts in all categories, except for CED and ADP, for which the main contributors are metals used for cabinet and electronic components. Regarding the operation of the URFC system, the energy supplied by PV panels dominates all impact categories due to, first, the resources and energy consumed for PV manufacturing and then, the 90% of the water that could be recovered during each cycle, impacting for less than 0.01%.

generators, characterized by crucial manufacturing or use phases (Mendecka et al., 2020). In addition, since URFC systems have not reached a mature development and application, different scenarios on operation management and end-of-life strategies have to be carried out. For example, future studies could estimate: i) the impacts of alternative renewable energy technologies accomplished on the URFC system, ii) the effects of using the heat produced instead of purging it into the environment, iii) the effects of bifunctional cell degradation on the maintenance phase or the impacts of a useful life longer than ten years.

However, to evaluate the accuracy of future LCA results, uncertainty analysis on missing reliable inventory data has to be carried out. Since research on URFC is still limited to experimental analysis, researchers, engineers and industry have to work hard to develop valuable documents that could help LCA practitioners carry out reliable life cycle inventory, collecting and identifying representative data on URFC manufacturing and end-of-life treatments.

Decarbonising heat-grids through interactive decentral prosumers

Alina Anapyanova

Decarbonising heat-grids through interactive decentral Prosumers

Problem impulse:

Integrating decentral renewable heat energies into new and existing heat grids creates significant potential in achieving climate neutrality and achieve sustainable development goals: ***SDG 7 , SDG 11, SDG 12, SDG 13.***

However, the process of decarbonisation in the building sector and heat-grids in Germany lacks momentum, innovations in technology and business models do not currently prevail.

Heat-supply strategies have thus to be reconsidered due to the current gas supply-shortages in the context of Ukraine-War and the Climate Crisis.

Research context:

A clear regulatory framework for a collaborative heat supply through decentral Prosumers in heat grids is missing.

Suitable Business Models for Prosumer-Heat grids in Energy-Communities are needed.

Conflict of interests arises between the current Business Modell Heat Grids Operators and integrating potential decentral renewable Heat Sources/Prosumers.

Business and Organisation Models have to be planned in cooperation with the Electricity Grid Operators (flexibility-services).

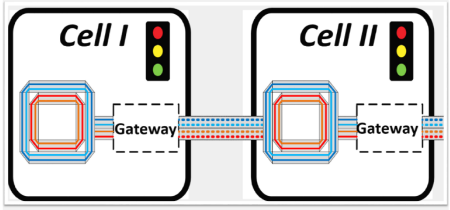
Due to the geopolitical crisis resilient energy systems should be designed responding to external and internal shocks.

Context needs:

*How to foster the **transformation-potential** for Energy-Communities through regulatory adjusments and economic incentives?*

*How to create **suitable technical and economic framework** or decentral renewable energy prosumers in existing heat grids (with **sector-coupling** utilities)?*

*How to design **cellular heat-grids**?*



Graphics: Meyer, 2022 (Interactive Heat Grids)

Research methods

- Actor-oriented approach based on the homo oeconomicus institutionalis
- Field research (interviews, monitoring of project implementation)
- Research follows an interdisciplinary orientation (law, economics, technology)
- Delta-Analysis helps to assess the status quo constellation from an "ideal state" perspective.
- Theory of Change allows a visioning of change (Activities-Output-Impact Assessment).
- Multi-Level Perspective Analysis analyses different dimensions and aspects influencing the successful implementation of Prosuming-Innovation in Heat Grids.

Assessment criteria:

Climate neutrality

Integrating renewable heat sources and prsoeumers allows a new potential for decarbonisation of heat-grids (solar thermal, waste heat, geo thermal energies).

Energy eficiency

Integration of decentral heat sources often demands specific technical requirementsto be fulfilled.

Electricity-grid compatible

Peak-Shaving and Load-Shifting through the flexible use of Heat-Pumps Heat-Grids: flexible energy storage for electricity can be achieved.

Use of locally produced and renewable power for heat pumps allows for a further decarbonisation and energy efficiency.

Actor involvement

Role as "prosumer" offers a high potential of willingness to participate in the change.

Energy communities offer a suitable environment for a collaborative heat-supply systems with prosumers.

Resilient

Diverse energy sources can foster resilience (also in times of geopolitical crisis).

Integrating decentral renewable heat sources has to be balanced with a goal of a stable energy supply.

Research question:

What adjustments to organizational and regulatory framework conditions are recommended with regard to the goal of climate-neutral integration of decentralized heat sources and storage systems into heat-grids?

CO2 as Important KPI in the 21st Century for Corporate Performance

Professor Tineke Lambooy[1,2,3], Drs. Rebecca Scholten[1]

[1]nyenrode business universiteit, breukelen, Netherlands. [2]utrecht universiteit, utrecht, Netherlands. [3]airlangga universitas, surabaya, Indonesia

Abstract

The scientific data on climate change urge for a transformation of the business models of the private sector: CO2 emissions must be avoided or neutralised. Governments can play a role in this transformation by changing the rules for the private sector. Besides that role, the private sector itself shows initiatives in introducing new business models. Institutional investors, consumers and NGOs also influence the behaviour of companies. As Lawrence Lessig of the New Chicago School argues in his 'pathetic dot theory' (1998) that law, social and cultural norms, the market and architecture (technical infrastructure), are all regulators of behaviour.

Shell, the Dutch-British oil & gas company, was ordered in 2021 by a Dutch Court to change its business model in order to reduce the CO2 emissions caused by all of its activities, including its upstream and downstream activities, by 45% by 2030.The figure of 45% relates to international scientific predictions as to what is necessary in terms of reducing CO2 emissions in order to stay within the internally agreed-upon Paris limits. Subsequently, Shell changed its strategy and communicated new CO2 targets, i.e. different from the targets it had published in the previous years.

In this paper, data are collected from Shell's and several other European oil & gas companies in their public communications concerning their CO2 emission goals. The focus of the paper limits the research to the years as of 2016, i.e. the year after the Paris Agreement was agreed upon. An analysis is made concerning the KPI CO2: did corporate targets change in the years 2016-2021 and (how) were such targets subsequently achieved? What is the motivation presented by such companies for changing their targets? Was any explanation provided for not reaching targets? if that was the case? Did any laws or court cases influence this?

The methodology is doctrinal combined with a comparative case study analysis. The data are collected from publicly available information such as annual reports, shareholders' communications and the companies' websites. Finally, the pathetic dot theory of Lessig is applied to reflect on the regulators of any changes found concerning the KPI CO2 in the communication by the selected companies.

Economic Assumptions Informing the Climate Change Scenarios of Australian Corporations

Ms Angela Bruckner[1], Dr Sebastian Thomas[2]

[1]University of Melbourne, Melbourne, Australia. [2]Curtin University, Perth, Australia

Abstract

Climate change is a major threat to businesses due to physical impacts of extreme weather and long-term environmental change and the regulatory and financial risks associated with carbon pricing, insurance costs, and the potential for corporate assets to be stranded. Increasingly, company directors are being held liable for these climate risks in corporate strategy. In response to pressure from shareholders and regulators, firms are considering how best to identify, evaluate, and disclose the commercial risks of climate change to their businesses.

The Taskforce on Climate-related Financial Disclosures (TCFD) has recommended that corporations publish a number of disclosures designed to inform investors and other interested stakeholders of the corporation's exposure to risks relating to climate change. One key recommendation is that corporations undertake scenario analysis against climate scenarios, including (at a minimum) a 2-degree scenario. However, the TCFD has identified scenario analysis as the recommended disclosure with the lowest level of implementation by organisations. Among the top 100 publicly listed companies in Australia, by 2019 only 10 of 72 firms operating in climate-exposed sectors have undertaken scenario analysis on either their entire business or significant segments of their operations.

This paper examines the economic assumptions underpinning the publicly available scenarios used by corporations. The results show a wide variety of climate-related scenarios and targets, and scenarios in which underlying assumptions have been modified to better suit corporate circumstances. Some scenarios may overstate future economic growth rates over the medium term, and many analyses explicitly exclude potential economic impacts of climate change. Although there is evidence of some degree of corporate engagement with scenario analysis, there is insufficient transparency regarding the assumptions drawn from publicly-available scenarios, with implications for the comparability of these corporate disclosures. There is also little evidence that engaging in scenario analysis has influenced the long-term strategy of the companies considered.

Managing Sustainability in Arts and Culture Organisations: The journey of Nottingham-based SMEs as change actors

Dr Ana Rita Domingues, Dr Muhammad Usman Mazhar, Ms Sarah O'Boyle, Professor Richard Bull

Nottingham Trent University, Nottingham, United Kingdom

Abstract

Arts and culture organisations play an essential role in society as educators, places to maintain and share values and social interaction. Even though arts and culture organisations are associated with significant impacts on the environment, society and economy, they are rarely considered in corporate sustainability research. Arts and culture organisations can be active actors in education for sustainability and drivers of change by empowering individuals and groups. They also play an essential role in the journey to decarbonise and decolonise the art world. The present research aims to understand better the experience of arts and culture organisations on corporate sustainability. It identifies drivers and barriers to implementing sustainability strategies and management systems and the crucial role of leadership and sustainability champions in organisational culture for sustainability management. This study conducted survey questionnaires and semi-structured interviews with key stakeholders in arts and culture organisations based in Nottingham, England. Art galleries, theatres and museums are used as case studies. Qualitative data was collected and analysed through content analysis. Internal documents and regulations were analysed to critically understand how the external socio-political and legal context impacts arts and culture organisations. Findings show that organisations supported by Arts Council England must account for their carbon equivalent emissions, which influences their chances of receiving funding. The socio-political context has significantly impacted their engagement in sustainability-related initiatives to guarantee access to resources. The internal culture and leadership in line with sustainability values play a crucial role in adopting changes to improve primarily environmental and economic performance. However, changes are primarily cosmetic, not involve transformational changes. Actions rarely result from a sustainability strategy or policy and are not supported by a sustainability management system. Some sustainability principles in arts and culture organisations mainly result from funding requirements and leadership and organisational culture for sustainability management. The proposed contribution relates to this year's ISDRS Conference theme by addressing how sustainable development is managed in arts and culture organisations. Specifically, it addresses how the traditional mention of sustainable development as ecological, economic and social dimensions is being interpreted across arts and culture organisations and its implications for society. The present work especially relates to the SDG 9 Industry, Innovation and Infrastructure (mainly, target 9.4) and SDG 12 Responsible Consumption and Production (particularly, target 12.2, 12.5,12.6, 12.7, 12.8).

Sustainability in Public Institutions in Germany: Enablers and barriers to organisational change in cultural production and basic services organisations

MA Coco Klußmann

Technische Universität Dresden, Dresden, Germany

Abstract

L'art pour l'art as credo for the production of a high cultural good (such as theatre) is still a prevalent idea, whereas a public basic service organisation (such as a wastewater plant) is supposed to be naturally sustainable. But what happens, if you introduce ideas of sustainable development into the very veins of such organisations? As part of a city-wide project "Future City", a theatre and a wastewater plant took part in the transition experiment "venture sustainability" in 2020/21 and their process has been researched in a qualitative case study. For this, expert interviews have been conducted with opened ended guideline questions, which has been triangulated with participatory observation.

The fact that art can catalyse sustainable development by i.e. artful (education) practices or content that is related has been well discussed in existing literature. On the other hand, dealing with wastewater is in itself a sustainable practice, directly related to SDG 6. Complementary this, I will argue, that introducing ideas of sustainable development to an organisation, is foremost a social innovation to that respective organisation's culture. Regardless of the instrumental potential or the "product" that is produced (be it high culture or basic service) or the fact that public institutions should be aligned with governmental governance concepts (such as the SDG), this comes rather as a shock to an organisation, as existing structure, procedures and practices of resources' allocation are under suspicion to be contested. So, to answer the question how and with which force such an innovation can be introduced and eventually woven into existing organisational structures, the involved actors' power struggle top-down and bottom-up has to be traced. Resolving this power struggle is a question of the organisations' identity involving the specific mode of (co-)management and respective imaginaries.

This abstract directly tackles SDG 16.7. as it investigates the process of responsive, inclusive, participatory decision-making of the involved organisations. Indirectly, SGD 12.2./12.5./12.8. are included in the process of the theatre and SDG 6.5. in the wastewater plant's process.

This abstract relates to the conference's topic in the way that it sheds light on art in the sense of the cultural industry, taking into account that art is not only a small scale "nice to have" that can be made use of as a vehicle or medium for sustainable development. Art as part of cultural institutions such as public theatres are an essential part of a society's communication and education system and thus are less "free" and easy to make use of as they are sometimes supposed to be when considered as "just making arts".

Sustainability Leadership of Social Entrepreneurs: The Driving force for sustainable development

Ms. Reeti Kulshrestha, Prof. Arunaditya Sahay

Birla Institute of Management Technology, Greater Noida, India

Abstract

The leadership is increasingly coming under the radar for being at the centre stage of driving the planet, people, and profit sentiment. Sustainability is the new strategic imperative that has caught momentum and the responsibility lies with the leadership to address the socio-economic-environmental sustainability at its core. Sustainability is no longer a buzz word but has become an essential part of national, community and corporate life. Right leadership is required at every level, especially at the top of the organization. Of late, social entrepreneurs have become the frontrunners in this sustainability movement. We find the traditional and social entrepreneur to be working on opposite directions causing socio-economic tensions. In either case, sustainability leadership is needed. While the traditional business is well researched with regard to sustainability leadership, little research has been conducted to look into the sustainability leadership of social entrepreneurs. It, therefore, becomes important to explore how social entrepreneurs practice sustainability leadership and achieve sustainable development goals.

Our paper brings in a new perspective by examining the work carried out by social entrepreneurs applying the 5I model of sustainable leadership (Mazutis and Abolina, 2019) that focuses on the five critical leadership tasks namely inspirational work, integrative work, identity work, implementation work and institutional work. Collecting data from five social entrepreneurs using semi-structured interviews, we illustrate how their work leads to sustainable development thereby contributing to the SDG goals.

Sustainability Management Initiatives in Non-Profit Organizations: An integrative review

Susana Trindade[1], PhD Fellow Natacha Klein[1], Prof. Dr. Tomás B. Ramos[2]

[1]CENSE–Center for Environmental and Sustainability Research, Department of Environmental Sciences and Engineering, NOVA School of Science and Technology, NOVA University Lisbon, Campus de Caparica, Caparica, Portugal, Costa da Caparica, Portugal. [2]Universidade Nova de Lisboa, CENSE, Center for Environmental and Sustainability Research, Costa da Caparica, Portugal

Abstract

Non-Profit Organizations (NPOs), also called "third sector" organizations, have an increasingly important role in society, especially in the current global changes context, including the pandemic situation and the new environmental, health and socio-economic challenges. The Social Economy sector is characterized by being a considerable contributor to national income and expenditure, as well as a significant employer. These institutions provide various human services, from health and education to social and community development services helping children, young people and families, supporting social and community integration and providing assistance to the elderly and disabled. Most of the time, they fill a gap in many areas that the governments don't provide. As for the environment, there is no country that is not experiencing the drastic effects of climate change. It is important to use the environment and its resources rationally and protect the Earth. Governments, the corporate and private sector, as well as the third sector must be on the same page to overcome these challenges. NPOs have been studied from different perspectives including the financial, managerial, leadership, social impact, performance, marketing, procurement, innovation perspectives. However, there is a general lack of knowledge on their sustainability practices and strategies at the organizational level. Consequently, this research aims to provide a systematic overview and analysis of existing sustainability management initiatives in NPOs. The research method was a systematic and extended literature review involving academic and non-academic contributions on organizational sustainability and NPOs found through international scientific databases, in particular, Scopus, Web of Science and google scholar. A qualitative content analysis was conducted to explore the selected documents. The results of this research are now being analysed, but preliminary findings showed that the literature covering organizational practices and strategies in NPOs is still limited.

Corporate Governance and Non-financial Disclosure: A bibliometric and critical review

Naciti Valeria[1], Pulejo Luisa[2], Rupo Daniela[3]

[1]*University of Messina, valeria.naciti@unime.it*
[2]*University of Messina, luisa.pulejo@unime.it*
[3]*University of Messina, Daniela.rupo@unime.it*

Abstract

The Sustainable Development Goals set out in the 2030 Agenda have the merit of having introduced an expansion of the concept of sustainability, no longer focused exclusively on the environmental dimension, but on a set of conditions that are fundamental for the pursuit of the general well-being of the community. In this context, the pursuit of sustainable economic growth can no longer be considered a slogan for companies to propagate. It now represents a binding objective, the concrete realization of which requires the integration of sustainability in the process of defining corporate strategies and the adoption of transparent and comprehensive accountability tools. In the recent years, in the context of reporting problems related to sustainability, there have been numerous legislative interventions and contributions from the scientific community that have determined an expansion of the information content of the traditional economic and financial reporting prospectuses produced by companies. Despite the critical issues still present in relation to the Corporate Sustainability Disclosure, virtuous paths have also been outlined by companies that are increasingly aware of the social role they play in the current economic context, of their social responsibility (CSR) for results and impacts deriving from the actions carried out and the values that guide the choices of economic governance. For companies that aim to compete on the market the adoption of "socially responsible" behaviour and the promotion of best practices today appears to be an obligatory and no longer voluntary choice. This awareness has favoured the use of tools, first the social report, capable not only of feeding the control system, accounting for the sustainability of the actions carried out and representing and communicating the "social value" generated but also, to foster dialogue with its stakeholders and obtain their consent and, finally, to support decision-making processes and to guide government decisions. The paper intends to examine the link between corporate governance and non-financial disclosure by means of a bibliometric analysis, a theoretical research method of a quantitative nature that allows identifying the most relevant scientific contributions, defining specific research areas and their interconnections, and therefore identifying the main research trajectories of the investigated topic, thus highlighting the different paths that scholars have taken in the past to connect the area of corporate governance with that of non-financial reporting. From the analysis emerges that with or without legislative obligation, the recognition of social responsibilities in the company is essential to outline the position and value of the same in the territorial, political, and social system with which they interact. There is more. It can be seeing more and more clearly how a progressive convergence is developing between processes, tools, and models of voluntary and mandatory disclosure. And how the process of institutionalization of non-financial reporting practices is inextricably linked to the profiles of governance.

1 Introduction

The evolution of corporate governance and management models, as well as of measurement and reporting tools, can contribute to meeting the social and environmental expectations of stakeholders, combining where possible the improvement of income performance. Furthermore, the social dimension of corporate responsibility, which involves stakeholders in defining the lines of action ¬and forms of communication (so-called stakeholder engagement), must also consider the potential for new environmental and social dissemination initiatives.

In this context, non-financial information is destined to become one of the most widespread tools, through which information is disseminated to business interlocutors, useful for evaluating the concrete commitment of the company in the social dimension (Ho, 2020). This business-environment communication system requires structural and coherent relationships between the corporate mission and corporate governance and constitutes an integral element for its management, according to a logic of coordination in which the mission makes the corporate purpose explicit; corporate governance identifies the corporate governance structure, and the declared social responsibility represents the information objectives (Naciti, 2019).

Furthermore, governance control contributes to the creation of value improving the quality of external information, including the use of voluntary information, thus helping to reduce the information asymmetry between those who participate directly in the management and those who are excluded from it.

The quality of non-financial reporting and its consistency with actual practices are also strongly linked to corporate governance (Poddar et al., 2019). Indeed, it defines principles, rules and procedures that influence the way in which a company is managed, administered, or controlled by managers in the interest of investors. Corporate governance is therefore linked to CSR as it aims to create value for both shareholders and other stakeholders (Morhardt, 2010). In this direction, the new provisions of the Directive are orienting corporate conduct towards greater dialogue with more stakeholders and introducing new structures and mechanisms of corporate governance.

In this interpretative framework, the last part of this monographic work intends to examine the link between corporate governance and non-financial reporting by means of a bibliometric analysis, a quantitative theoretical research method that makes it possible to identify the most relevant scientific contributions, define specific research areas and their interconnections, and therefore identify the main research trajectories of the topic investigated.

Following the methodology proposed by Van Eck and Waltman (2010), in this section we proceed using text mining and clustering analysis based on the co-citation of the literature in the years from 2016 to 2021. This methodology allows us to identify the main theoretical blocks of the field studied, revealing the type and intensity of the connections existing between them, thus bringing to light the different paths that scholars have taken in the past to connect the area of the corporate governance with that of non-financial reporting.

This study essentially consists of a three-stage analysis process: the first step concerns the acquisition of data, including the search for those of a bibliographic nature. The second phase consists of the examination of the items (publications) obtained using a specific software (VOS Viewer, the potential and analysis tools of which will be described below). Finally, in the last phase, the conclusions of the research are converted into networks analysis that can be further interpreted.

Quantitative analysis using bibliometric indicators and a database of citations returns important information on the values relating to the impact of each scientific contribution published by the relevant scientific community. In this sense, ¬bibliometric analysis can be used to identify research gaps and provide guidance for future investigations on the topic. Additionally, bibliographic data is used in this type of analysis to establish internal links in the literature, analyse citation and co-citation levels, and algorithmically discover clusters.

2. Research design

2.1 Data selection

Data selection follows the five principles proposed by Kipper et al. (2019) and the bibliometric procedures he explained in order to obtain the datasets.

The first criterion concerns the selection of the database, it is carried out among all the best known and complete ones: Web of Science (WoS), Science Direct, Scopus, Medline and Embase. However, database coverage is a key priority in this study to unravel the evolution and conceptual structure from previous literature investigated in the two most cited databases such as WoS and Scopus. Therefore, the same search strings were used in the two databases and, finally, the database containing a greater number of publications than the other, namely Scopus, was selected. The latter is periodically updated with entries of articles from thousands of international publishers, subjected to peer reviewing processes: in fact, more than 2300 Open Access are indexed, and it is possible to export metadata and publications belonging to different research fields.

The second criterion concerns the choice of the time interval: this study proposes as a time reference the years following the issue of Directive 2014/95 / EU on non-financial reporting obligations. The third criterion relates to the accuracy of the search terms to be selected: corporate governance, integrated reporting, non-financial disclosure, social reporting, sustainability reporting, environmental reporting, social accountability, voluntary disclosure, mandatory disclosure. Each search term has been quoted in order to apply the logical operators "AND" and "OR" to refine and extract the search results. The fourth criterion concerns the selection of the type of documents. Scientific articles are predominantly favored by researchers. In this procedure, the filters made available by the database are used.

Finally, the last criterion concerns the selection of bibliometric software: in this regard VOSviewer to other software since it provides a clear visualization of the data and has a high compatibility with the metadata

2.2 Methodology

With the rapid advancement of data mining, information analysis, and graph rendering technologies, it is now possible to evaluate huge volumes of literature data using software programs and to "express" the data through its visualization. In this study, the VOSviewer software was used , it is a software that allows you to create and view econometric networks, allowing you to identify the main topics that have been treated in the past (keyword analysis), the most cited papers in our sample (citation analysis), the studies that were most cited by the papers of the sample monster (co - citation analysis), journals , authors, organizations that appear more frequently in the literature.

Basing ourselves on keyword analysis, the frequency with which a topic appears in the literature, as well as the co - occurance models, reflects the importance of the same. The size of the circle (node) indicates the number of times the keyword has appeared, and the colors denote which cluster it belongs to. In simple terms, the importance of a keyword is only the frequency with which it appears in publications. The strength of the connections between two key words, say i and j , is the number of elements, each of which contains both key terms in the title, abstract or list of keywords.

This approach, called unified, groups the data based on both the distance and the strength of the relationship between the nodes, with the following term reduced to a minimum:

$$V(x_1, ..., x_n) = \sum_{i<j} s_{ij} d_{ij}^2 - \sum_{i<j} d_{ij}$$

where sij denotes the strength of the association between keywords i and j calculated from:

$$s_{ij} = \frac{2mc_{ij}}{c_i c_j}$$

where ci is the total number of co- occurance of keyword i with all other keywords so that:

$$c_i = \sum_{i \neq j} c_{ij}$$

while m denotes the total number of occurrences for all keywords so that:

$$m = \frac{1}{2} \sum_i c_i$$

Note that ½ in the equation removes the double count between c ij and c ji .

$$d_{ij} = \begin{cases} 0 & \text{if} \quad x_i = x_j \\ 1/g & \text{if} \quad x_i \neq x_j \end{cases}$$

3 Results

3.1 The sample: descriptive analysis

Following the above criteria, 411 articles were identified, with an average of 9.04 citations per article and an h-index of 30.

Figure 1 shows the total number of publications between 2016 and 2021, more precisely all the articles published up to September 2021. It is evident that the theme of corporate governance and non-financial reporting has refined over time. In fact, in 2016 the number of published articles was rather low (34), subsequently, the scientific community has intensified the interest on ¬the subject, enriching the debate with a growing number of publications. The peak is in 2019 with 93 publications. It should be noted that the trend of publications decreases from 2019 to 2021, in fact in 2020 we record a decrease of 8.61%. This could be due to the impact of the Covid-19 pandemic on scientific publications in this area. The urgency to fight the virus has in fact pushed researchers and scientific journals to disseminate studies on the Covid-19 topic much faster than normal and with free access, thus cutting out studies that did not address these issues.

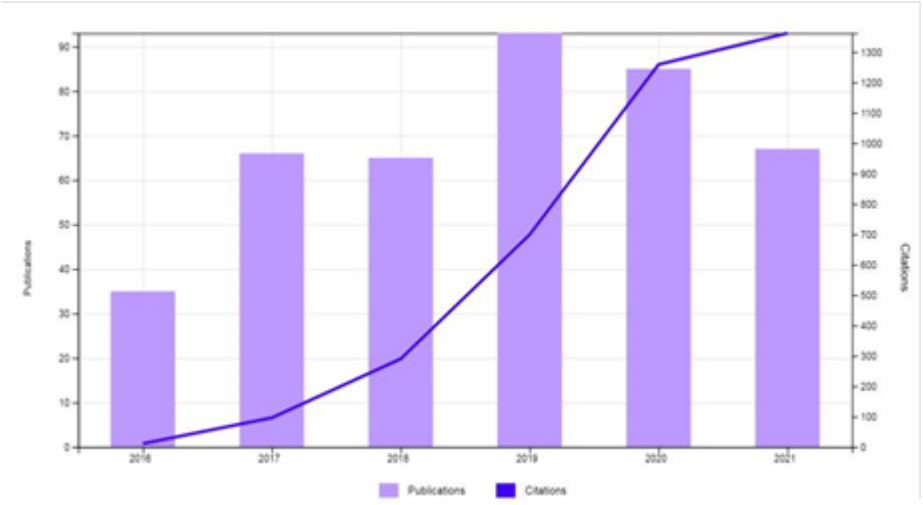

Figure 1. *Trend of publications and citations*

Table 1 shows the top ten countries with the highest number of articles published. The top three contributors in terms of publications are the United States of America (49), England (48) and Italy (40). Interestingly, the remaining publications from other countries (Australia, Malaysia, Spain, the People's Republic of China, South Africa, Tunisia and Indonesia) provide a lower academic contribution. This may be linked to the lack of knowledge and dissemination of the topic together with the non-mandatory application of environmental standards, as well as the importance assigned to the reporting system at national level.

Table 2 shows the research institutes that have published a minimum of five articles. Compared to table 1

they have more articles and citations. The reason for this is that any single American research institute has no more than three articles. The top ten affiliations contribute 73 articles, equal to 17.8% of the total number of publications (411).

Table 1. *Top ten nations in terms of number of publications*

Country	*N. publications*	*No citations*
United States of America	49	453
England	48	507
Italy	40	656
Australia	30	365
Malaysia	30	235
Spain	28	330
China	21	135
South Africa	18	297
Tunisia	18	87
Indonesia	15	37

Table 2. *Organizations with at least five publications*

Organization	*N. publications*	*Quotes*
University of Portsmouth (England)	9	84
University of Sfax (Tunisia)	9	32
Salamanca University (Spain)	8	124
University of Witwatersrand (South Africa)	8	124
University of Auckland (New Zealand)	7	203
University of Southampton (England)	6	101
Huddersfield University (England)	6	138
Mansura University (Egypt)	5	75
King Abdulaziz University (Jeddah, Saudi Arabia)	5	22
University of Valencia (Spain)	5	74
University of Salento (Italy)	5	61

Most of the research institutes with the highest number of publications are located in Europe with universities in England (University of Portsmouth, University of Southampton, University of Huddersfield), Spanish (University of Salamanca and University of Valencia) and Italian (University of Valencia). Salento) with a total of 39 publications. Therefore, there is a concentration at European level of institutions that study aspects related to corporate governance and non-financial reporting. This is attributable on the one hand to the similarity of the legislation of European countries, on the other to the fact that, recently, the Brussels Commission presented a legislative proposal to modify the Directive on non-financial reporting. The new legislation that derives from it, the Corporate Sustainability Reporting Directive (CSRD), is aimed at expanding the number of companies that must comply with the Directive; this indicates that in the coming years, European research institutes will increasingly address the issue of non-financial reporting as a necessary condition for regulatory compliance.

Among the non-European institutions, the University of Sfax in Tunisia stands out with 9 publications, the University of Witwatersrand in South Africa with 8 publications, the University of Auckland in New Zealand with 7 publications, the University of Mansoura in Egypt with 5 publications and King Abdulaziz University in Jed dah, Saudi Arabia with 5 publications.

Table 3. *Authors who have published at least four documents*

Authors	*N. publications*	*No citations*
Hussainey, Khaled	8	60
Raimo, Nicola	7	102
Vitolla, Filippo	7	102
Ntim, Collins G.	6	138
Maroun, Warren	5	115
Ruby, Michele	5	102
Agyei-Mensah, Ben Kwame	4	40
Jarboui, Anis	4	36
Pizzi, Simone	4	61
Rodrigues, Lucia Lima	4	87
Velte, Patrick	4	138

Table 3 shows the authors who have published at least four research contributions. The authors do not present in the list have not reached this minimum threshold and therefore it is believed that the scientific research disclosed does not have continuity of themes and temporal references. This affects the current progress of research and the evolution of corporate governance and non-financial reporting issues: where some authors still have a single publication, it is believed that particular attention is lacking on the topic, which translates into an attention gap that it is expected to increase in the years to come. The authors who submit at least 4 publications are all university-educated, which demonstrates that the interdisciplinary link between scholars other than the university (non-university research bodies and, in particular, bodies responsible for defining the regulatory framework ¬and of reference self - regulation). In this perspective, it is noted that instead it would be desirable, in the opinion of the writer, for the research to arise from an interrelation between scholars of the problem and those who are responsible for issuing regulations, guidelines on non-financial reporting and academics.

Table 4 shows the top ten journals in terms of publications on the topic ¬. Relating the number of citations to the number of articles disclosed in column 3, we read that Business Strategy and the Environment has the highest number of citations (276), followed by Corporate Social Responsibility and Environmental Management (239), Corporate Governance the International Journal of Business in Society (192) and Meditari Accountancy Research (123).

Table 4. *Top ten journals in terms of the number of publications*

Journal	*N. publications*	*Quotes*
Sustainability	18	94
Corporate Governance the International Journal of Business in Society	15	192
Journal of Financial Reporting and Accounting	15	32
Business Strategy and the Environment	12	276
Journal of Applied Accounting Research	12	88
International Journal of Disclosure and Governance	10	43
Journal of Management & Governance	10	70
Corporate Social Responsibility and Environmental Management	9	239
Journal of Accounting in Emerging Economies	8	72
Meditari Accountancy Research	8	123
Accounting Research Journal	7	23

From the analysis of the journals, it emerges that the scholars' approach to the theme of corporate ¬governance and non-financial reporting is multidisciplinary and develops along two main lines. The first concerns highly specialized journals on the topic of environmental sustainability (Sustainability, Business Strategy and the Environment, Corporate Social Responsibility and Environmental Management), while the second concerns journals that investigate the profiles of Corporate Governance and Accounting (Journal of Financial Reporting and Accounting, Journal of Applied Accounting Research, International Journal of Disclosure and Governance, Journal of Management & Governance, Journal of Accounting in Emerging Economies, Meditari Accountancy Research and Accounting Research Journal).

This result testifies to the orientation that has been developing in recent years to consider the issue of so-called non-financial reporting as an integral aspect of financial reporting, therefore not as something subsidiary to the latter, but as a reporting area intended for dialogue and interconnect with traditional financial reporting.

3.2 Data processing and network analysis results

The program used for bibliometric analysis allows you to conduct network analysis. Thanks to a software potential that allows you to create and view bibliometric maps, VOSviewer it can in fact be used to build maps of scientific journals or authors using co-citation data, as well as keyword maps based on co-occurrence data. The software uses a specific mapping technique to create clusters.

3.2.1. Keyword analysis co-occurrence

The keyword co-occurrence network analysis determines which terms were frequently used in the sample papers. This type of analysis helps to understand what kind of topics and ¬problems scholars are most interested in. The VOSviewer creates a map, with the distance between the terms taken as an indication of the relatedness of the various keywords. The more two or more terms appear to be related, the smaller the distance between them. Co-occurrences in the articles were examined to establish the correlation of terms

Figure 2 shows the keyword co-occurrence network map, where the numerous keywords linked together by various lines are presented.

Figure 2. *Keyword co-occurrence network map*

The lines indicate that these crucial headwords appeared together in multiple items. Thus, the terms that have been used most often indicate that more searches have been done in certain areas (Table 5).

Table 5. *Top ten key words in terms of frequency*

Rank	*Keyword*	*Frequency*
1	Corporate Governance	333
2	Voluntary disclosure	220
3	Performance	123
4	Mandatory disclosure	95
5	Ownership	86
6	Board of directors	85
7	Information asymmetry	78
8	Integrated reporting	72
9	Corporate social responsibility	62
10	Financial performance	53

The keyword co -occurrence network map (Figure 2) shows three main clusters, which can be distinguished by their colours: “red cluster”, “green cluster” and “blue cluster”. Although the results of the keyword cluster analysis suggest that the clusters should be considered formally separate, in the corporate literature the topics addressed by the two groups of publications are logically linked and strongly connected.

Starting from the red cluster, we see words such as corporate social responsibility, performance, accountability, integrated reporting, disclosure, environmental disclosure, stakeholder theory, sustainability, non-financial reporting, etc.

The basic assumption of CSR is the concept of accountability, i.e. the ability to communicate one's social commitment to the vast audience of stakeholders, as well as to shareholders in a complete and transparent way. The analysis shows that in recent years, many scholars have focused their attention on the profile of CSR and sustainability reporting, which has now become the subject of transversal and multi- form investigation. In particular, the previous research has addressed the need to give an account to the stakeholders of the results achieved as well as the wider impact of a different nature that their activity determines on the reference context, and today we can affirm that the growing diffusion of the social responsibility tools to which we are witnessing is due to the progressive recognition of CSR by companies operating in various sectors and geographical contexts (Kolk, 2008).

Furthermore, in the red cluster the significant importance of integrated reporting issues becomes evident, in close connection with the disclosure and performance aspects. These three keywords make up the largest nodes in the cluster. It should be noted that this strong link finds clear explanations in terms of the research results developed in the last six years:

on the one hand, the flourishing of studies and experiences on integrated reporting is fuelled by the recognition of the standard for the purpose of the regulatory obligation of non-financial disclosure;
on the other hand, the most recent studies are particularly aimed at investigating the link between financial performance (financial performance is another relevant issue) and CSR performance. Among other things, the issue of disclosure is significant for judging the quality of reporting and at the same time represents, in many studies, an attribute that enters the metric used to estimate non-financial performance (level of disclosure as a proxy of the level of social performance).

As widely discussed in Chapter 1, in addition to having a purely economic dimension, the company's activity also has a socio- ¬environmental dimension that impacts on the reality of various actors, that is, the stakeholders. Furthermore, through its strategic-reflective role, the communication function has a greater effect on corporate behaviour than in the past.

Through a high degree of coherence and synergy of all corporate communication initiatives, external expectations, as well as management and production actions, the corporate reputation is in fact strengthened. Non-financial reporting therefore assumes the dual significance of being an effective tool for informing company policies in terms of enhancement and protection of human, natural and social resources,

a corporate management image that has the consent of the community, enhancing reputation, which is critical to generating the company's broader public trust.

From the bibliometric analysis, another research topic emerges relating to the mechanisms of corporate governance, sustainability and environmental disclosure (the green cluster in Fig. 2). There are two main reasons for thinking that corporate governance mechanisms are important for environmental performance. First, substantial investments and long-term strategies are required for sustainability of performance, and this implies a major impact on the capital structure and profitability of the company. Secondly, the natural environment requires multiple ¬levels of coordination, both at the organizational level and involving the entire supply chain and other stakeholders. Therefore, governance becomes more applied to a broader form of monitoring of business activities that includes the impact on the environment and on society.

This additional aspect often arises in response to stakeholder requests and can potentially create tensions and conflicts between shareholders, boards of directors and CEOs, as it requires them to take on corporate responsibilities in a new way (Rao and Tilt, 2016). The benefit that derives from the adoption of eco-friendly strategies in the corporate context is represented by the so-called sustainable profit.

Sustainable profit is linked to the creation of direct economic value; therefore, the practice of enhancing environmental impact has become increasingly widespread. Therefore, pushing companies to adopt sustainable strategies does not only mean embracing ethical responsibility, but rather the positive returns that derive from it in terms of economic performance, organizational efficiency, competitive capacity and reputation improvement make it particularly attractive. Consequently, it is clear that sustainability can become an integral part of governance strategies by being part of the analysis of best practices. The difficulty of quantifying spill overs in real terms of sustainable strategies is due to the nature of the resulting benefits, which are mostly made up of intangible assets. These elements guarantee the company the ability to create a profile based on image enhancement, product quality or brand reliability.
From this analysis it emerges that this cluster of publications is closely related to the previous one, as regards the fraction of publications relating to sustainability reporting and voluntary reporting. In fact, as expressed above, sustainability reporting allows companies to evaluate and quantify the results of sustainability strategies in general, and of CSR policies in particular, allowing a tangible quantification of the intangible benefits deriving from sustainability.

Another theme that appears, both in the red and in the green clusters, is that of the characteristics of the board of directors. In fact, the cluster shows words such as board composition, women, CEO duality, board independence, board size and diversity.

In this sense, the board of directors is understood as the most important governance mechanism within the company and therefore its composition, in terms of gender, age, nationality and professionalism of the members is considered a determinant of the organisation's performance. in general, and of sustainability strategies, in particular. Boards of directors have generally been studied as a homogeneous group and, likewise, business practice has usually overlooked the importance of board composition and its

past decade, researchers have focused on evidence regarding the role of boards, particularly their efficiency. More recently the attention to the diversity of the board of directors has increased: the corporate governance reflects a balance between the various solutions proposed within the ¬company. Indeed, according to the theory of social and psychological dynamics, within ¬the board of directors there could be compensatory effects between directors ¬belonging to (gender) minorities such as to affect the performance of a company. Many authors have found that diversity of boards of directors ¬can provide organizational benefits ranging from competitive advantages, for example, to pursue stronger marketing strategies or attract stronger human resources, to better performance. According to previous literature, diversity can be defined as the variety of the composition of the board related to observable demographic aspects such as gender, age, ethnicity, nationality, cultural background, religion and degree of independence and other less visible ¬aspects (such as education, professional experience in the sector, skills).

Finally, in the blue cluster the most frequent word, which is the only one in the ranking of the top ten keywords, is mandatory disclosure. However, the areas of investigation covered, their foundations and the research methods provided by scholars are rationally interconnected in the scientific community. In fact, the smaller number of elements displayed in the blue cluster is offset by the interaction with the red and green clusters. The focal point of the blue cluster is' mandatory reporting association and information asymmetry. As a background to this link, we coherently trace some of the most important words of this cluster agency cost. Following this interpretative scheme, the links with the theme of value relevance are well understood, intended to investigate the effects on the market of non-financial information (market effect), i.e. the response in terms of the market value of equity with respect to the disclosure of non-financial information.

In fact, in the face of poor information efficiency, greater communication is required through continuous and timely information flows to the market, which can limit opportunistic behaviour of the subject. In these uncertain conditions of contractual quality or incompleteness and moral hazard, corporate information is entrusted with the role of information and reporting functions. Communication plays an informative role when it offers the client the opportunity to make rational investment and divestment decisions in advance, in order to choose which agent to negotiate with and to what extent the level of discretion granted is compressed. On the contrary, when it offers the opportunity to verify the decision made by an economic entity (agent), it performs a reporting function. Furthermore, due to the discretion to adopt non-financial reporting standards, the various procedures envisaged for the determination of materiality can create information asymmetry and strongly question the ability of organizations to guarantee the comparability of non-financial information in the same economic sector and / or in the same reference context (Legislative Decree no. 254/2016 on non-financial reporting).

Therefore, disclosure of non-financial aspects was mostly a voluntary practice adopted by companies in response to stakeholder expectations and to gain legitimacy. However, several studies have shown that the quality of voluntarily reported information is rather poor, does not correspond to effective and responsible behavior and is a symbolic management practice.

Hence, governments and the EU have become aware of the ineffectiveness of voluntary disclosure, which results in unbalanced, inaccurate, inconsistent and incomparable information (CE, 2013). As a result, many countries have started requiring mandatory non-financial disclosures. The latest regulatory intervention refers to the non-financial EU Directive, which modifies the "soft" obligations included in the previous Directives (2003/51 / EU and 2013/34 / EU).

As reported by the same Directive, the EU promotes corporate responsibility and increases transparency which in turn promotes the trust of stakeholders (mainly investors and consumers) and, consequently, the access of companies to their resources. The EU assumes that companies comply with ESG disclosure requirements because this results in positive legitimacy and / or economic gain.

For a more detailed analysis of the evolution of the search from 2016 to the present, a separate survey was conducted on the chronological appearances of the keywords ¬. Figure 3 shows the weighted average year of occurrence of the keyword for 411 papers. From 2016 to September 2021, the transformation from blue / purple to dark green, light green and yellow shows the average years of occurrence of the keywords. The change in this time frame reflects the evolution of the corporate governance and non-financial reporting theme. Overall, it can be observed that the blue / purple cluster contains the main keywords of the previous literature: corporate social responsibility, sustainability, stakeholder theory, diversity and csr disclosure.
The green cluster highlights pioneering studies on the topic of non-financial reporting by focusing on the aspects concerning the relationships between integrated reporting, corporate governance, voluntary disclosure, environmental disclosure, information asymmetry. More recently, however (words in yellow), issues such as board composition, executive compensation, earnings, discretionary disclosure, ceo duality, equity, risks and accountability have emerged.

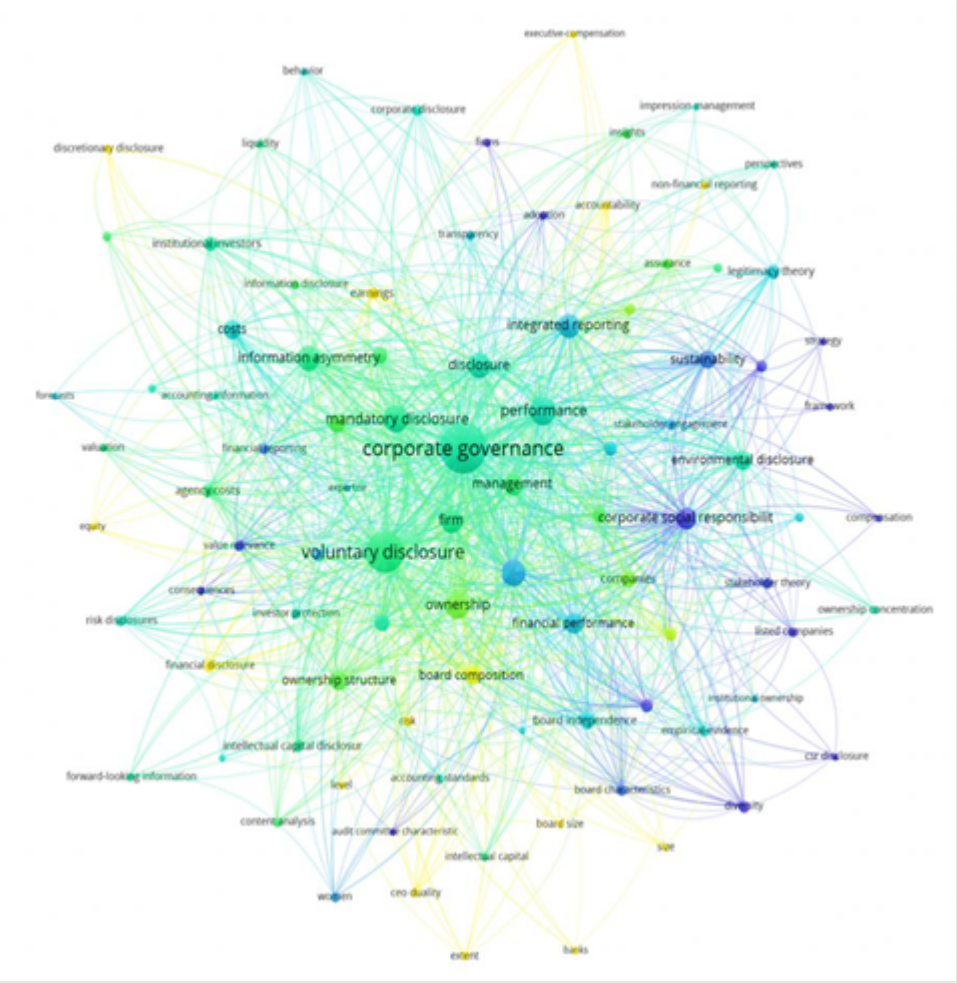

***Figure 3**. Overlay Keyword co-occurrence network map*

3.4.2. Analysis of citations

Even in the business area, the number of citations is often used to monitor the relevance and scientific effect of the research. According to De Villiers and Hsiao. Consequently, a high citation index for a research publication typically denotes that it has had or will have a major effect in the area.

Table 6 shows the most cited sample papers. The first article was published by Hussain, Rigoni, Orij in 2018. The study empirically investigates the relationship between corporate governance and the triple sustainability performance (economic, environmental, social) through the lens of agency theory and stakeholder theory. The results of this study contribute to the improvement of the ongoing standards definition process, as regards the in-depth review of the economic dimension of sustainability carried out within the GRI framework.

***Table 6.** Top five publications in terms of citations*

Title	*Authors*	*Quotes*	*Year*
Corporate Governance and Sustainability Performance: Analysis of Triple Bottom Line Performance.	Hussain N .; Rigoni U .; Orij RP	163	2018
The economic consequences	Barth ME; Cahan SF; Chen Li;	127	2017

associated with integrated report quality : Capital market and real effects .	Venter ER		
Diversity of Board of Directors and Environmental Social Governance: Evidence from Italian Listed Companies.	Cucari N .; De Falco SE; Orlando B.	111	2018
The association between integrated reporting and firm valuation .	Lee K .; Yeo GH	106	2016
What are the drivers of sustainability reporting? A systematic review.	Dienes D .; Sassen R .; Fischer J.	88	2016

In the second article by Barth et al. determine whether previous research that found a positive association between integrated report quality and enterprise value is actually true. The authors find no evidence of a relationship between integrated report quality and cost of capital but find that higher integrated report quality is associated with greater investment efficiency.

The third paper by Cucari et al., investigates the association between environmental, social and governance (ESG) disclosure and board diversity in Italian listed companies. Their research findings show that disclosure of the company's CSR is associated with the CSR of an independent director and committee. Furthermore, women on the board are negatively correlated while the age of the board is not significant.

The fourth article was published by Lee and Yeo, the authors examine the -association between integrated reporting and corporate valuation, using a sample ¬of listed companies in South Africa. They show that company valuation is positively associated with integrated reporting disclosures. According to the authors, this result suggests that the benefits of Integrated Reporting outweigh its costs.

In last position with 88 citations, we find the paper by Dienes et al. The manuscript systematically examines existing studies and analyses the drivers of sustainability reporting using a qualitative approach. The review suggests that firm size, media visibility and ownership structure are the most important factors for disclosure of sustainability reports, while corporate governance appears to have an influence only on the existence of audit or control committees. sustainability.

3.2.2 Analysis of co-citations

Co-citation analysis is a useful tool for determining the structure and evolution of a topic. We speak of co-citation when two separate publications are cited through a third article. The goal of this type of analysis is to uncover a hidden pattern of relationships with authors based on their publications, such as revealing authors who have not actively collaborated but have been referenced by other articles at the same time.

As in other network analyses, the multiple lines starting from each node reflect the co-citation frequency of the authors and the thickness of the nodes represents the strength of the co-citation bonds.

Figure 4 shows the co-citation analysis map. It is possible to observe the presence of three clusters of different colours (red, green, and blue). They are strongly interconnected with each other, in particular the blue one is grafted into the red and green clusters.

Figure 4*. Co- citation network map*

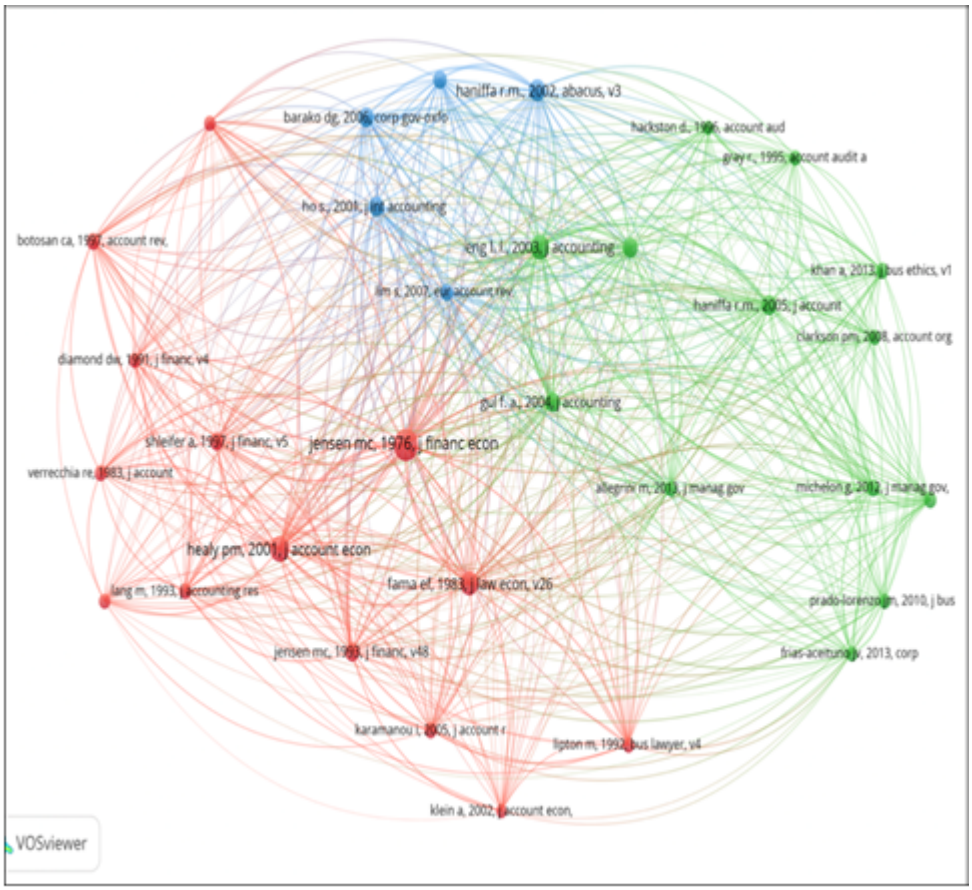

Table 7 shows the top ten most cited publications that are present in the co-citation analysis cluster. The ranking is presented in order of citation, where citation refers to the number of publications in the sample citing the paper.

Although the table is presented in order of citation, from the most cited to the least cited, it is more useful to comment on the works in chronological order (from the most remote to the most recent) to understand

Title	*Number of items in our sample that mention the document*	*Cluster*
Jensen MC, Meckling WH (1976), *Theory of the firm: Managerial behavior, agency costs and ownership structure* , Journal of Financial Economics.	163	Red
Healy PM, Palepu KG (2001), *Information asymmetry, corporate disclosure, and the capital markets: A review of the empirical disclosure literature* , Journal of Accounting and Economics.	107	Red
Eng LL, Mak, YT (2003), *Corporate governance and voluntary disclosure* , Journal of Accounting and Public Policy.	97	Green
Fama EF, Jensen MC (1983), *Agency problems and residual claims* , The Journal of Law and Economics.	91	Red
Haniffa RM, Cooke TE (2002), *Culture, corporate governance and disclosure in Malaysian corporations* , Abacus.	78	Blue

Table 7 - *Top five publications in terms of co-citation*

The first study is therefore that of Jensen and Meckling (1976) - red cluster - considered the pioneering work on agency theory, which has been the theoretical basis of most accounting and corporate governance studies. The work identifies the way in which the agency problem arises, providing a definition of what they call agency relationship: " ... a contract under which one or more person (principal) engage another person (agent) to perform some service on their behalf which involves delegating some decision-making authority to the agent. If both parties to the relationship are utility maximizers, there is good reason to believe that the agent will not always act in the best interests of the principal (Jensen and Meckiling p.33). Basically, the authors analyze the contract in which the principal gives the agent the power to act on his own and clarify the possible consequences of the characteristics of this agency relationship. They verified how the person in charge (agent) has greater discretion in the choice, that more information on the principal (asymmetric information) can be used for personal gain rather than for business, and it is not entirely because the remuneration is linked to the result. of the activity. This "asymmetry of power" between the two counterparties of the contract creates an opportunistic form for the agent identified as information asymmetry and moral hazard, which can lead him to maximize his own usefulness and therefore pursue a relationship with others. Produce the so-called "agent problem ". This is the fundamental role of the corporate governance: the agency problem should be limited by corporate governance mechanisms whose execution involves agency costs.

The second, more remote, article is that of Fama and Jensen (1983) - cluster red - in their study argue that independent directors, providing both professional skills ¬and monitoring activities, can add value to the business ¬. Furthermore, according to the authors, private property should reduce agency costs because property rights are largely restricted to "internal decision makers" whose personal involvement ensures that

allocation of resources. Finally, family management should further reduce agency costs because the shares tend to be held by "… agents whose special relations with other decision agents allow agency problems to be controlled without separation of the management and control decisions. For example, family members… therefore have advantages in monitoring and disciplining related decision agents " (Fama and Jensen,1983, p 306).

The third position, in chronological order, is occupied by Healy and Palepu (2001). The authors find that voluntary disclosures are more relevant to investors than mandatory disclosures, especially when voluntary disclosure: "Firms provide disclosure through regulated financial reports, including the financial statements, footnotes, management discussion and analysis, and other regulatory filings. In addition, some firms engage in voluntary communication, such as management forecasts, analysts 'presentations, and conference calls, press releases, internet sites, and other corporate reports. Finally, there are Disclosures about firms by information intermediaries, such as financial analysts, industry experts, and the financial press " (Healy, KG Palepu , 2001. p.2).

In 2002, Haniffa and Cooke (2002) examine the importance of various corporate governance characteristics (cultural, race and education), as well as company-specific factors ¬, as possible drivers of voluntary non-financial disclosures in the annual reports of Malaysian listed companies.
Finally, the study of Eng and Mark (2003)- green cluster - which occupies the third position in terms of citations examines the impact of ownership structures and the composition of the board on voluntary disclosure. According to the authors, managerial ownership and blockholder ownership are two main governance mechanisms that help control agency problems. Their findings show that less managerial ownership and significant government ownership are associated with increased disclosure.

4. Discussion and Conclusion

Corporate governance mechanisms and non-financial reporting has increased significantly in recent years. By means of this survey it was intended to provide a first verification of the theoretical assumption in order to better understand the knowledge base of the research line investigated.
Several relational approaches based on existing publications on the topic (441 articles) were used in bibliometric analysis, including citation analysis, keyword co-occurance analysis, and co-citation mapping analysis (Waltman et al., 2010).

Several implications of the current study emerge that should be addressed. The first implication is based on a deeper knowledge of the governance tools related to non-financial reporting. From the analysis of keywords and papers in terms of citation and co-citation , it emerges that this relationship is influenced both by internal mechanisms that are attributable to the board of directors (both in quantitative and qualitative terms), to the figures of the CEO and the chairman of the board, to the audit committee and to ¬any presence of other committees (risk committee), the management incentive and remuneration policies; and external mechanisms, i.e. the action of external stakeholders other than shareholders, the managerial and outside labour market directors.

On closer inspection, the internal and external controls, and responsibilities of the board of directors are the result of interventions and recommendations aimed at supporting corporate policies based on a single environmental, social and governance (ESG) standard according to a single keyword: transparency of information favours long-term sustainable development, and it is in this context that sustainability involves multiple themes in a horizontal and complementary manner.

In addition, as the chronological analysis of keywords shows, the most recent research that addresses the issue of corporate governance and non-financial reporting seem to be interested in analysing how each component of corporate governance influences corporate sustainability practices (Michelon and Parbonetti, 2012)., strategies, and performance. Surely, these aspects should be investigated, both by addressing additional and new dimensions (for example, cultural variable in multinational companies), by analysing the interaction between individual aspects, and by studying how diversity is reflected in the formulation of communication strategies. In this sense, diversity management has been on the organization's agenda since the early 1990s, with numerous managers and scholars arguing that diversity has both a long and short-term impact on various business dimensions.

The most important elements in determining a corporate governance model capable of protecting the holders of property rights are the number of independent directors, the presence of sub-committees, the separation of offices between CEO and Chairman and, finally, the number of shares held. by the administrators. In fact, a board composed of many directors would have difficulty in coordinating its activities and would not allow the active participation of all members, thus determining ineffective monitoring action. Furthermore, the division into sub-committees increases the supervisory power of non-executives and the separation between the Chief Executive Officer and the Chairman should ensure greater independence of the administrative body. The analysis shows how all these aspects have recently been associated with sustainability practices and performance. In particular, the scholars have shown that the corporate governance structure should allow mechanisms to improve not only the financial performance of the company, but also its sustainable performance, supporting wider stakeholder participation. Additionally, lenders will be more likely to interact with companies that show greater sensitivity to sustainability initiatives. In turn, through the concept of corporate sustainability, the role of the board of directors goes beyond the idea of simply maximizing shareholder well-being, as it also includes an ethical approach to stakeholders.

Co-citation analysis revealed, most studies in this ¬field primarily base their considerations on stakeholder theory, agency theory, and legitimation theory. On closer inspection, these theories provide a snapshot linking corporate governance mechanisms and non-financial disclosure by focusing on the crucial role of the board. The board is, in fact, the main corporate decision-making body which has the task of controlling the conduct of executives and of addressing, in a balanced way, the interests of the various stakeholders through the implementation of adequate strategies and disclosure policies that embrace both financial matters than non-financial matters. However, the effectiveness and efficiency with which the board pursues its monitoring and reporting tasks strictly depends on the set of skills, competences, experiences, and

based on an adequate composition of the board of directors with regard to the diversity of its members. Indeed, men and women have different personalities, socio-cultural backgrounds, leadership styles, skills and expectations which, when properly combined, can enrich discussions and improve decision-making within the board.

Stakeholder theory, as well as agency and legitimacy theory, are certainly useful for addressing issues related to the functioning of corporate governance structures and mechanisms and their effects on reporting, but they are of less help when it comes to analysing aspects. more specific. For example, the need to transform (translate) a corporate sustainability strategy adopted at the level of the board of directors into concrete actions by the company's employees should be addressed by specific organizational theories. Similarly, how the diversity of the composition of the board affects the board's decision-making process regarding non-financial reporting appears to be an aspect that cannot be addressed by leveraging only the theories of stakeholders and agencies; rather, psychological or organizational behaviour theories might provide useful insights in this regard. This aspect can undoubtedly constitute an in-depth topic for carrying out subsequent research.

Finally, corporate governance, understood as the institutional framework that regulates the process of formulating and implementing corporate decisions, it is constantly evolving: this debate is destined to be constantly renewed, because on the one hand the issue is subject to regulatory evolution and on the other, they are the same actors to change their behaviour in order to create value.

Evolving Purpose towards Sustainability

A maturity model on how purpose implementation enhances corporate sustainability

Abstract

In uncertain times, companies face difficulties in achieving corporate sustainability. The academic literature indicates that sustainability can be achieved through the implementation of corporate purpose, but does not indicate how. In this article, we present a maturity model that, in three stages, seeks to address this question. Strategy is a fundamental aspect, especially in the early stages, and seeks to adapt the business model around the purpose. It also shows the actions for leadership to be deployed in the company until it reaches all employees. Other actions, later on, correspond to the use of human resources systems to ensure the impact of the purpose on sustainability; and the role of communication to make it all work. It also illustrates what sustainability outcomes can be expected at each stage, and what employee behaviors are affected by implementation. It is therefore not only a theoretical contribution that answers the question posed above, but a practical contribution to companies. The maturity model will help them to understand the implementation process, and the actions in it will help them to choose the right path.

Keywords: Purpose Implementation, Corporate Sustainability, Maturity Model, Focus Group, Corporate Purpose

1 Introduction

Today, companies find themselves in a precarious position for the survival of their business. We see this, for example, with the crisis of confidence among customers and governments (Hollensbe et al., 2014), the competition for resources, and the increase in competitiveness (Gartenberg et al., 2019). In addition to these economic problems, companies receive pressures to have a positive impact on the social and environmental environment (Engert et al., 2016), especially after the economic crises and the Covid-19 pandemic (Sharma et al., 2020).

Therefore, economic, social, and environmental sustainability has become a fundamental aspect for companies (Dyllick & Muff, 2016). Corporate sustainability is difficult to define, but most definitions include an improvement in economic and social performance and a decrease in environmental impacts

(Meuer et al., 2020). This is known as the triple bottom line (Bansal & Song, 2015), and this is the definition we will refer to in this paper as corporate sustainability.

Over the past 30 years, academia has produced an enormous amount of research on corporate sustainability (Feil et al., 2019). Of particular relevance is how to ensure that companies generate this positive impact in the long term (Benn et al., 2014). To this end, previous studies have pointed out two fundamental aspects: the unity of the different stakeholders around the company, and the inclusion of sustainability in the company's strategic decisions (Engert et al., 2016; Husgafvel et al., 2015; Hutchins et al., 2019).

This is no easy task (Kiron et al., 2017), and it has been pointed out that one of the main assets facilitating these two processes is corporate purpose (Dyllick & Muff, 2016; Jimenez et al., 2021). The corporate purpose is understood as the company's raison d'être (Mayer, 2020), as the objective beyond profit (Henderson & Van Den Steen, 2015). Purpose has value as a unifying element among stakeholders and is able to contribute positively to each of them (G. George et al., 2021), what connects it to sustainability.

But corporate purpose has another advantage: the entire company can be articulated around it, creating the purpose-driven organization (Quinn & Thakor, 2018). This means that the elements incorporated into the purpose are present in the company's strategy, leadership behaviors, systems, and communication, among other aspects (Lleo et al., 2019). The real power of purpose is not for companies to have it, but to live it in the daily operations (White et al., 2017), in a process known as purpose implementation (Lleó et al., 2021). It has been postulated that this implementation is necessary for the purpose to have an effect (Rey et al., 2019). The greatest impact observed in the implementation is in the behaviors of employees, because they are the ones who carry out the activities that contribute to the impact of the purpose (Lleó et al., 2021).

However, although authors have identified the various ways in which purpose relates to sustainability, *how* this implemented purpose generates sustainability has not been explored (Jimenez et al., 2021). We performed a review on how previous research have had addressed the impact of corporate purpose on sustainability, and we discovered that it is usual to relate them, but no study had delved on how purpose-driven companies achieve this sustainability (Ruiz-Pérez et al., 2022). This is why in this article we aim, based on the need for purpose implementation, to explain how to create a sustainable purpose-driven organization.

This process is long, and requires multiple actions on the part of the company (Rey et al., 2019). Therefore, we believe that the best way to address the challenge of explaining how the implementation
of purpose makes the company more sustainable is through a maturity model. A maturity model presents the evolution of a system over time in a series of maturity states (Cuenca et al., 2013). They are helpful because they guide in a process by clarifying the activities to follow (Mettler, 2011).

2 Methods

Once the need for this maturity model has been identified, it is advisable to define the scope of the model (Mettler, 2011). There are different ways to tackle this task. There are maturity models, for example, to assess strengths and weaknesses, or tools that compare the company's activities with the best practices

specific aspects or on general descriptions (Mettler, 2011). They can also be used to guide improvement initiatives and monitor progress in a pragmatic way (Iversen et al., 1999; Röglinger et al., 2012). That is, not so much looking for a picture of what the perfect company looks like, but to help understand how to move forward in a complex process (Mettler, 2011).

We aim in this research to help companies to implement the purpose to generate sustainability, so we will take this last perspective of maturity models. Wanting to facilitate purpose-driven companies on their way to sustainability, we will seek to make a model that presents the actions aimed at implementing purpose, and justifies a rationale for the emergence of sustainability consequences.

Therefore, in the model, the maturity levels will differentiate between the actions to be developed to implement the purpose and consequences of sustainability. The basic levers for implementation are strategy, leadership, systems and communication (Lleo et al., 2019), and the sustainability consequences are extracted from a previous study that defined employee sustainable behaviors and economic, social and environmental sustainability at a corporate level (Ruiz-Pérez et al., 2021).

To design the model, different authors propose qualitative approaches that are capable of capturing the complexity of maturity (Mettler, 2011), and also not to do it from a theoretical point of view, but close to those people who are applying this in their day-to-day life (Correia et al., 2017). For this reason, the development will be carried out through two focus groups.

The focus group methodology is defined as the research technique through which information is collected through the interaction of a group with the topic proposed by the researcher (Morgan, 1996, p. 130). This methodology is good for delving into how processes occur (Kitzinger, 1995). This aspect is particularly relevant to us at this stage of the research. It is also a methodology that allows for discussion among participants in order to elicit common knowledge across different contexts (Nyumba et al., 2018).

However, this restricted the selection of participants. It was not possible to choose a random sample of companies, since the topic requires knowledge of the management and strategic vision of the company. Therefore, we resorted to a selection of a specific audience that could provide the knowledge we were seeking (Nyumba et al., 2018), as recommended in these cases (Tong et al., 2007). We contacted the human resources managers of purpose-driven companies that we had assessed and had seen a high degree of implementation among the workforce.

Table 1. *Information of the focus group participants*

Position	Company size	Company sector	City (Country)
Head of Social Responsibility	50 employees	Medical services	Paterna (Spain)
CEO	100 employees	Iron & Steel Industry	Manresa (Spain)
Head of Human Resources	250 employees	Chemical industry	Tarragona (Spain)
PR & Communication Manager	unknown	Automotive	Tondela (Portugal)
Head of Social Responsibility	600 employees	Logistics	Dos Hermanas (Spain)
Head of Human Resources	250 employees	Textile	Alcoy (Spain)

Eight companies were contacted in November 2021, of which two had to leave the process due to scheduling problems. Table 1 shows the composition of the focus group participants. There is no fixed number of participants in a focus group, which varies between two people and two dozen (Nyumba et al., 2018). The most common proposal is usually between four and eight people (Kitzinger, 1995), a requirement that we fulfill.

We decided to divide the focus groups into two, for reasons of schedule and intellectual effort. The first session addressed how the levers implement the purpose; and the second how companies generate sustainability consequences. The researchers provided material in advance to the participants, reminding them of some key concepts and presenting the first activity to be done in the focus group (Tong et al., 2007). Due to the physical distance between companies, it was decided to use an online focus group modality, and participants were informed that these sessions would be recorded for later analysis.

The main biases of this methodology appear when a single individual orients the conversation with his charisma towards his opinions, or when the most shy people tend to avoid giving their opinion because it is dissenting (Mukherjee et al., 2018). To avoid these biases from the outset, the six participants were divided into two groups of three, each with a moderator and a listening researcher to assist the moderator if the discussion got out of focus. Each group was asked to brainstorm on the actions that could be taken to implement the purpose from the strategy. Afterwards, a discussion was opened in which they explained why this action was important, and at what level of maturity it was necessary to carry it out. This was done for strategy as well as for leadership, systems and communication.

Once both groups had identified the actions and had assigned them to levels through a discussion, both groups were brought together. First of all, both results were compared, looking for coincidences and opening a debate on the differences of opinion. Subsequently, the moderator pointed out aspects that
may not have appeared and the reason for this absence. This was also done by separating strategy, systems, leadership, and communication

The second day, also conducted remotely two weeks after the first, was different. Previous research, especially the mentioned previous study (Ruiz-Pérez et al., 2021), had produced a list of sustainable behaviors and three lists of corporate sustainability variables. Therefore, the brainstorming phase was not necessary and the assignment of maturity levels for the sustainability consequences proceeded directly.

3 Results and Discussion

The maturity model presents three stages of maturity of the purpose implementation:

Stated purpose: is the most immature stage of purpose-driven companies. At this maturity level, or stage, companies have defined what their purpose is and have made a public statement showing it. However, there has been no implementation throughout the company.

Initial Implementation: is the intermediate stage of maturity. At this level, the company has taken a series of actions to ensure that the purpose is lived in day-to-day actions and decisions are consistent with the

before the purpose statement. Nor do all employees have the purpose in place, and it is possible that there are still inconsistencies between what is stated and what is lived.

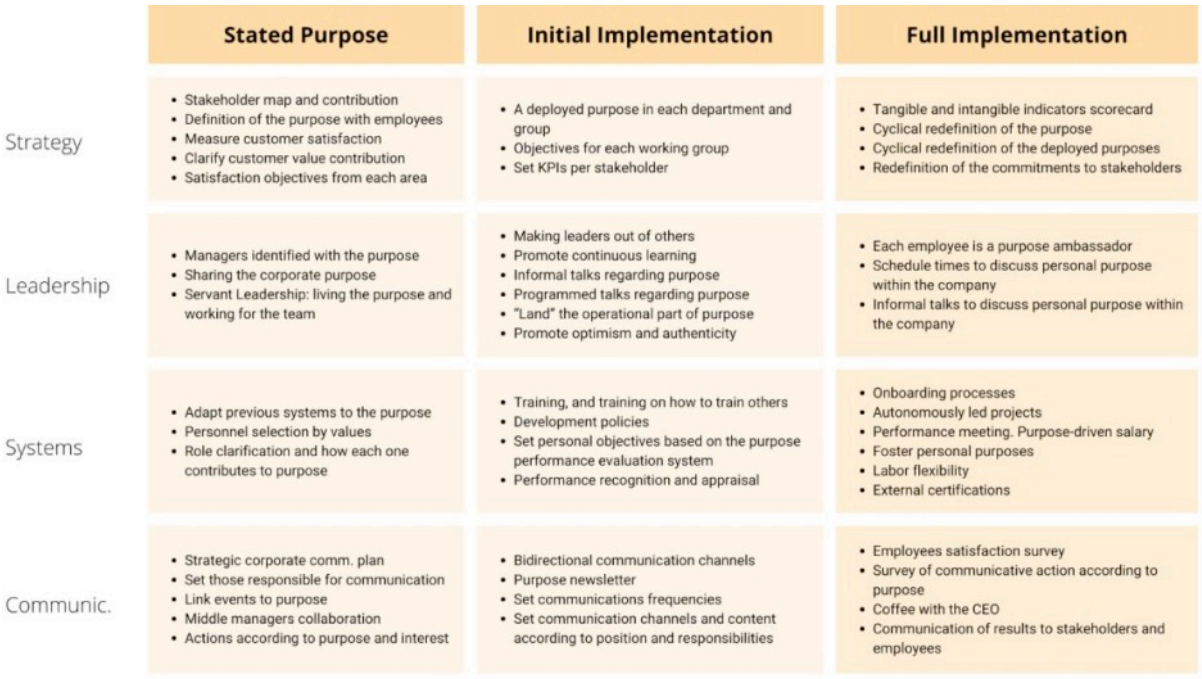
Full Implementation: the stage of full maturity of the purpose implementation. At this level, all company decisions are aligned with the purpose; all interactions with stakeholders and all operations are conducted with the purpose in mind; and all employees share the purpose, making it applicable to their jobs.

One of the objectives of the actions of the maturity model is to help complete the definition of these maturity levels. Thus, these descriptions given above are complemented by the actions extracted by the experts, as we will now see.

3.1. Purpose Levers

To implement the purpose, we rely on strategy, leadership, systems and communication. The actions indicated by the experts are shown in Figure 1.

Figure 1. Maturity Model for the Purpose Implementation. Own elaboration



Strategy

Before considering the purpose implementation, the experts commented that a purposeless strategy is focused on revenue. One of the changes that the purpose brings is the search for a contribution to society, to colleagues, to the planet. This requires −before the purpose statement− a map of stakeholders and the impact that can be had on them. This preliminary work does not study what impact the company *wants* to have on these stakeholders, as this will be done once the purpose has been defined. It is only a matter of locating the stakeholders that surround the company.

The experts also recommended conducting customer satisfaction surveys to observe what they value about the company, and thus be able to establish the differences between what the company expected and what it is achieving. The company, through the image that customers have of it, can observe what differentiates it from the competition and support its purpose.

However, as noted by the experts, this approach is becoming more and more common at the company's foundation. Companies that are born in this competitive environment and under strong environmental legislation are often aware of their own identity. This does not imply that they live this identity in all aspects of the company, or that their strategic operation is aligned with the purpose, but they already have this differentiation more defined. In none of the six participating companies had this been the case; all of them were born as a classic company.

indicated that this is usually done with group dynamics of all employees, but that prior work is necessary on the part of management. This prior work should guide these exercises towards the discovery of the purpose.

I. Stated Purpose

In this stage, the company has done the work of defining the purpose with the employees, making them participants of the new stage in the company. Not only that, but in light of the purpose, strategic documents such as the company's mission, vision, and values should also be updated.

The management must now clarify the contribution to each stakeholder identified in the previously developed stakeholders map. The purpose shows what contribution the company wants to have, but it must have specific contribution proposals associated with it in order to implement it. The company must focus on the value provided to the customer.

The strategy is to make the purpose the center of the business model, which should be based on the contribution made to the customer. To do this, one of the possible means is a discussion in each work area on how value is provided to the end customer. Each area should set objectives to achieve customer satisfaction.

II. Initial Implementation

With these actions, we would enter the initial phase of purpose implementation. Regarding the impact on stakeholders, the participants state that in this phase KPIs (Key Performance Indicators) should be associated to the different stakeholders in order to measure the impact on them. Later on, these KPIs will be used to monitor whether or not the objectives are being met.

Initial implementation is a phase in which the purpose is deployed throughout the company. This is done in the work groups, areas, and departments. In order to carry out the implementation, it is necessary for each of these groups to "particularize" the general purpose to their occupation. The experts commented that the best way to do this is in a top-down manner according to the divisions of the company. For example, if the company is divided into departments that in turn have areas that in turn have work groups, a "particular purpose" of the department should be done first. With this departmental purpose and the general purpose of the company, a purpose of each area should be realized collectively, and so on. This "roll-out" or "dissemination" has been noted in the literature (Malnight et al., 2019), we are not aware of it going so far as to specify that each work group should have a purpose that connects to the overall one.

But it is not only a matter of finding the purpose of each working group. The strategy must help implementation through a definition of objectives. These objectives should be discussed within the group, seeking consensus, and only if consensus is not reached should the person in charge decide. Regarding the monitoring of these objectives, some experts pointed out that they should be monitored on a monthly basis.

In short, for the initial implementation, objectives and indicators should be studied for stakeholders at the company level, and their fulfillment should be monitored. At the working group level, a purpose should be defined that stems from the corporate purpose, and objectives should be defined that are derived from the overall strategy.

III. Full Implementation

In this phase, a dashboard of tangible and intangible indicators should be set up in order to have updated information on how the company is performing and how its employees are doing.

But what the experts discussed most at this stage is the need to update the purpose and the consequences that this has. This has been little addressed in previous literature, and it is a point to which the experts gave importance. If the purpose is the identity and the contribution of the company, it has to be something that changes, because the environment is changing, the company is facing new problems, and therefore the impact it can have on stakeholders changes as well. Therefore, the definition of the purpose must be reviewed cyclically, although the experts did not propose an estimated frequency.

In the number of strategic actions that the experts discussed, it can be seen that the bulk of these occur in the purpose statement phase; with the initial implementation being an adaptation at the working group level, and the full implementation phase being the cyclical redefinition of the purpose.

Leadership

This aspect is one of the most discussed in previous literature (Cardona et al., 2019; Williams et al., 2014). It refers to the behaviors of managers, middle managers, and, in short, of all people with responsibility over others in the company.

A preliminary reflection of the experts consulted is that leaders in purpose-driven companies have similar leadership styles. Therefore, it does not vary much to belong to one or the other work group.

I. Stated Purpose

The first and most important action is that senior managers must identify with the purpose. This also extends to middle managers, even at such an early stage of implementation. In short, the point is that, as soon as there is a declared purpose, the leaders by hierarchy must have this identification. In fact, a case was mentioned in which, after seeing that he would not be able to identify with this purpose, a senior manager left the company. In terms of leadership, the company "cannot afford" to have leaders who do not identify with the purpose.

Beyond this identification, the experts also noted their role of dissemination, of "sharing the purpose"; that is, communicating it. In this regard, they mentioned that it was important to take advantage of the different occasions to remember what the purpose was and what could be done to live it.

But the most authentic way to communicate purpose is to "live" it. Both managers and middle managers must exemplify the purpose through their actions and decisions. The role of middle management is seldom

experts also considered that the fact that they identify themselves and set an example not only facilitates implementation, but that if this behavior is absent it makes implementation much more complicated.

This way of "living the purpose" is one of the defining characteristics of the leadership style expected in purpose-driven companies: servant leadership. These leaders are concerned that the purpose is alive in their actions, but they are also people who work for the team. In a way, they see in their team the possibility of operationalizing the purpose and, therefore, they are dedicated to their team.

II. Initial Implementation

Once the purpose is more implemented, and the different workers have adapted it to their work groups (as we saw in the strategy section), the leader is characterized by the promotion of continuous improvement within the company and its workers. They also promote optimism, sincerity, and contribute to all this with their own behavior. The ultimate goal of these actions is to generate new leaders; to make leaders among the workers under their charge.

It is also at this stage that the steering committee should include a discussion on purpose in its meetings. The idea pointed out by the experts is to share experiences to facilitate the transition to the purpose-driven company. In this section of the meetings, managers should talk to each other about how they are personally living the purpose in their jobs. This should also be incorporated into the meetings of the leaders of the different divisions of the company.

Also, leaders must be aware to lead not only by example but also by word of mouth. Take advantage of informal moments, meetings, to talk to workers about the purpose. Discuss it, comment on it, see the application in the day to day. Talk about the purpose and consider it as a criterion to find solutions to the problems that emerge.

III. Full Implementation

In this phase, as one expert remarked: "all employees are leaders, all employees are ambassadors of purpose". Therefore, they have to show the characteristics already mentioned: service, consideration of the purpose in all actions, promotion of the purpose with their example.

And there should also be continued scheduling of times throughout the company when the purpose is discussed. Employees should be able to talk to their line managers and peers about how they are living the purpose; in planned meetings as well as in informal conversations.

Systems

Purpose-driven companies take established management and performance appraisal systems and illuminate them with purpose.

I. Stated Purpose

It is important to adapt the different management systems to the purpose. The performance appraisal system must also be aligned. According to the experts, alignment means, for example, eliminating features that go

stakeholders must also be reflected in these management systems, especially commitments to employees. At this level it is also important to clarify the roles at every job post and how each job has a significant contribution.

A selection by values should also be started (if it did not already exist). As seen in the strategy, in this phase the mission, vision and values must be updated. Thus, candidates should be screened not only for their competencies, but for the meaning they can bring to the actions they are going to perform. The experts pointed out that this is progressive, since in the stated purpose phase the company-wide implementation has not yet begun, and therefore it is not advisable to focus on new recruits while neglecting those workers who are already there. Again, inconsistency could be detrimental.

II. Initial Implementation

In this stage, the performance appraisal system has to be applied in a definition of objectives for each of the workers. The leaders have to have meetings with the workers to define these objectives, based on the purpose. It is worth remembering that in this phase the adequacy of the purpose to each of the work groups has already taken place (see the strategy subsection).

It is also important at this level of maturity to recognize employees for their efforts to live the purpose. The experts' proposal was not only to recognize their performance, but also their effort and attitude. It was not clarified whether this recognition was to be given publicly or privately.

In a more organizational rather than personal way, professional and personal development policies should be pursued at this stage. These development policies must also be reflected in staff training. As indicated, training is not only the training to perform the job well (in accordance with the clarification of roles mentioned above), but also the ability to train new people. This training of oneself and others is not only on the professional and technical level of the job, but also on the aspects of purpose.

The aim of this employee development and their motivation by purpose-related objectives is to achieve in a more advanced implementation that the projects are led autonomously. This autonomy is given in the work groups. However, this autonomy must occur when the employees have the purpose implemented, and the leaders are in the aforementioned action of creating new leaders according to the purpose.

III. Full Implementation

Finally, most system actions are performed with a full implementation of the purpose. For example, the company should embrace an onboarding process. The purpose-driven enterprise is an organization in which everyone knows his or her place and contribution. This can make the first days of new incorporations more complicated, and so this onboarding is proposed, done by leaders and fellow workers, in which the job is explained to them, what is expected of them, examples of how to live the purpose, etc.

Also, the experience of purpose is reaffirmed with an aspect mentioned in the literature: the inclusion of personal purposes (B. George et al., 2008). The company must ensure that each employee connects the company's purpose with his or her personal purpose. And, if they have not discovered what their personal

purpose is, help them to do so. In this way, employees work for their own personal fulfillment by contributing to the company's purpose.

To observe how it has been meeting the objectives set based on performance according to the purpose, it is proposed at least an annual meeting with the immediate leader in which this performance is evaluated. All experts stated that there was retribution or recognition of some kind for meeting these purpose objectives. Approximately half of the companies surveyed had a financial reward bonus based on the objectives of the purpose.

Labor flexibility also arises at this level of maturity. In a full implementation, people know what they have to do for the company and what is necessary to dedicate both in time and resources. This gives rise to the freedom and autonomy that employees are given, depending on their job.

In order to finish with the systems, the experts agreed that it is advisable to obtain external certifications of the quality of the systems, such as, for example, the seal of equality. This will prevent the system from becoming accustomed to the fact that certifications require periodic reviews.

Communication

When asked what a communication without purpose looks like, the experts indicated that it results in a communication that does not have a narrative, is "messy", and, as a result, is not directed at stakeholders.

This means that the company does not make known the impact it has, nor does it propose the impact it could have.

I. Stated Purpose

Once the purpose is defined, this change. One of the first steps in the stated purpose stage is to elaborate a corporate strategic communication plan. This plan contemplates the most interesting communications according to the importance that the company assigns to its actions. This then has to be translated into communicative actions based on the purpose and the target interest group.

In more internal communication aspects, it is necessary to define those responsible for communication, and to make it clear that the different areas must collaborate with communication. As it is the phase of defined purpose, it is convenient that workers receive communication of the purpose not so much with explanations but with actions. Therefore, a fundamental communicative task is to link events and actions with the elements of the purpose and the values of the company

II. Initial Implementation

In this stage, the experts assigned actions only in communication towards employees. They defined as fundamental to create communication channels in both directions, such as social networks, e-mail, suggestion box, intranet... These channels can be simultaneous, since they will be used for different communication purposes.

One of these channels should provide a newsletter on the purpose, with a defined frequency. This newsletter

by the company in favor of the implementation, messages or testimonials from managers and employees, etc.

Finally, there must also be a guide that defines channels and the content of messages according to each employee's position. There can (and, according to experts, should) be communications only for specific areas, with different content from those that are carried out globally. And the company must have the capacity to achieve this. All the companies studied had some application or web service that allowed them to do this, both internally developed and outsourced.

III. Full Implementation

Communication in a full implementation is also very much directed at employees. One action that came up is a satisfaction questionnaire for all employees. This has to be done with a certain frequency and, the experts felt, with questions not only of general satisfaction but also oriented to the fulfillment of the purpose. Another necessary questionnaire is how employees view the communication actions according to the purpose. In other words, they should share their opinion on how they consider the company is doing its communication, knowing what the purpose is.

Also, as a disruptive element of hierarchy and vertical communication, the possibility of having a conversation with the CEO of the company was proposed. One of the companies followed a "coffee with the CEO" policy. Some experts wanted to generalize to senior managers, but those companies that had this communication action said that it was important and more useful if it reached the top manager of the company.

Finally, the company must communicate its results periodically with the indicators already developed. This communication must be made to employees and other stakeholders with whom a commitment has been acquired through the purpose.

3.2. Sustainability Consequences

We will analyze also how the purpose implementation generates sustainability consequences in four aspects: sustainable behaviors, economic sustainability, social sustainability, and environmental sustainability. The consequences indicated by the experts are shown in Figure 2.

Figure 2. Maturity Model for the consequences of Purpose Implementation. Own elaboration

	Stated Purpose	Initial Implementation	Full Implementation
Sustainable Behaviors	• Codes of conduct	• Water, materials, and waste reduction • Suggestions for the reduction of environmental impact • Work relations • Work performance • Innovation related suggestions	• Employee transport • Social grous • Employee wage
Economic Sustainability	• Risk and crisis management • Corporate Governance • Codes of conduct	• Economic Profit • Technology and Innovation	
Social Sustainability	• Employment of local population • Communication of environmental risk • Relations with suppliers • Equal opportunities	• Local community projects • Social innovations • Employee relations • Human Capital Development	
Environmental Sustainability		• Water, energy, emissions, materials, and waste reduction • Environmental impact of products	• Transport

Sustainable Behaviors

I. Stated Purpose

Compliance with codes of conduct appears in a phase of stated purpose, especially at management levels. The experts considered that the new definition of roles that takes place in this phase leads to a search for coherence and integrity, and that this aspect improves when the role in the company is better known.

II. Initial Implementation

Most of the sustainable behaviors appear in the initial implementation phase, although they are fully developed in the full implementation stage. For example, two economic behaviors that begin to bear fruit in the initial implementation are job performance and innovation suggestions. In the case of the former, the employee knows better what to do, and is more motivated to do it in order to reciprocate to the company. In the case of innovation suggestions, all the experts agreed that it was not an increase in the quantity of suggestions, but in their quality. Employees know their job better, but they also know the company, the processes, and what the company is looking for. This is why there is more impact on this behavior.

Purpose implementation also affects compliance with working hours. This sustainable behavior refers to employees complying with the hours they are required to work. This ensures social sustainability by ensuring that employees have a healthy work-life balance. The experts consulted reported that in purpose-driven companies, working hours are taken care of, and no one is expected to stay on overtime. However, from an initial implementation they felt that employees do not mind spending more time to finish their work. This is in line with studies showing that, when employees share the corporate purpose, they put in extra hours and effort.

Also, on social sustainability, a behavior that begins to be observed in this stage is employee relations. The

employees to care about each other as the purpose is implemented. Some will do it out of altruism, out of service, but even if this altruism is not present, employees know that helping others helps the company itself, and the impact it wants to have.

Another social sustainability behavior that appears in the initial implementation phase is that of actions by social groups. For example, in one company, Saturday mornings are dedicated to handing out hot breakfasts to homeless people in the nearest provincial capital. In another, they collaborate with high schools to raise awareness among students of the environmental challenges facing business and society. This is not limited to participation in activities that the company may have with stakeholders to whom it is committed; it is also the proposal of new activities by employees and the organization of these activities.

The initial implementation also includes environmental sustainability behaviors: saving water, reducing materials and waste, and suggestions for reducing environmental impact. The logic behind the suggestions is the same as in the innovation suggestions: the employee knows his or her job better and, therefore, the environmental consequences it may have. The suggestions are therefore more enriching. It is not the number that increases, said the experts, but the quality of the suggestions.

On water, materials and waste, the experts could not agree on the extent of the impact. Obviously, there is more or less impact depending on the responsibilities of the employee and the sector of the company.

All the experts indicated that it was necessary for management to comment that environmental sustainability was one of the company's objectives, and preferably stated in the purpose. In several cases, the company had had to support this message from the purpose. The recommendation made by the experts was to include the environment as a stakeholder with which to have a positive impact. If this were the case, water, materials, and waste would be reduced more easily and, above all, more widely among the workforce.

III. Full Implementation

Following these behaviors, the experts selected two variables that appear only when the company has already fully implemented the purpose. The first of these is the salary issue. There was dissension among the experts, since, as one indicated, "they are never going to be happy with their salary," but it did indicate that the emergence of purpose in the first phase decreased employee requests. They now had a transcendent motivation to deal with as well. However, with the purpose in place these demands reappeared, but this time as a function of the purpose objectives. As indicated in the systems, financial or emotional rewards should be applied at this stage for the performance of purpose-driven objectives. This is exactly what employees are demanding. Finally, it was also apparent (although not all experts agreed) that employees changed their means of transportation to get to the company. As they indicated, this depends on the location of the company and the possible alternatives. In short, the implementation of the purpose has a clear impact on the sustainable behaviors of employees, especially from its initial stage and with an increasing impact as full implementation is achieved.

Economic Sustainability

I. Stated Purpose

It starts having an impact from its statement, as it makes governance better. Experts attributed this to the fact that purpose makes it easier to navigate complicated environments with good corporate governance. In the end, it is all about aligning decisions with the purpose and, if the purpose is well stated, it makes it easier to question. By way of comparison, one expert noted that without a purpose the company may have good governance, but it does not usually consider the whole organization.

From the same statement, the impact on risk and crisis management is also noticeable. Having a purpose sets a course to follow, and uncertainties can be better resolved. In addition, according to the experts, the purpose statement already at the declaration stage creates a unity in the steering committee that makes it easier to make decisions in this area. Between a declaration phase and an initial implementation phase, the results would be seen by the codes of conduct, as has been seen to happen in employee behaviors. This is also based on the clarification of the company's values.

II. Initial Implementation

All other economic sustainability results appear in the initial implementation phase, although they are fully developed in the full implementation phase. Of these, the most characteristic is economic profit. The experts agreed that purpose-driven companies have higher profit, but that this only appears when the purpose is already being implemented. It may not be a noticeable improvement at the beginning, but it is already showing at this stage. With respect to the generation of technology and innovation, there is no radical change. A company that is not dedicated to it, such as a technological start-up, for example, will not see its number of patents increase by acquiring a purpose. However, according to the experts, processes are improving, and there is a spirit of continuous improvement among employees, which does improve innovation within the company.

III. Full Implementation

As mentioned above, all the variables on which the implementation or declaration has an impact increase their results in this phase.

Social Sustainability

All experts agreed on the logic by which impact on social sustainability was achieved. This logic is: the company's commitments to stakeholders directed the actions carried out in the levers, achieving these social results.

I. Stated Purpose

The impact on social sustainability aspects appears in the purpose statement. For example, the company's commitment to the environment in which it operates is reflected in two aspects: employment of local people, and communication of potential environmental hazards. The second aspect was more debated, as not all the companies had an environmental commitment to their local community.

The purpose also changes the way suppliers are treated. This is due to the fact that more aspects than

whose activity goes against what the company is looking for. Consistency is required from the earliest stage of the purpose-driven company. But it is also a positive aspect, since the purpose can make a competitive supplier more interested in participating in the company's activity. It also happens in the stated purpose phase equal opportunity. In purpose-driven companies there is commitment to employees. The company must take special care to favor all its employees equally. Promotional opportunities, for example, should be well communicated and accessible. For this action it was indicated that the development also continued with the different phases, improving each time and receiving feedback.

II. Initial Implementation

The other consequences of social sustainability appear in this phase. For example, local community projects are supported both financially and with the collaboration of the employees. This has been done in various companies through an NGO competition, in which they evaluated which of the various proposals was most in line with their purpose. As the turnover and capacity of some companies has grown, the number of projects supported has also increased. Social innovations are also being encouraged, as they are based on commitments to stakeholders.

On the employee side, it is at this stage that the relationship between employees is significantly improved. This has also been indicated in the section on sustainable behaviors. It is also in this phase that there is an improvement in human capital, sustained by two factors. First, as seen in the systems, the purpose increases the education and training given to employees, but it is also that the employees themselves participate in the process of transformation into a purpose-driven company.

Finally, two aspects of social sustainability are in dispute over whether the purpose has an impact or not. There are arguments for and against because of the experience of companies on whether the purpose improves relations with unions. Proponents that it does improve are based on the fact that the unions observe that the company is interested in the workers as well; but detractors believe that this is only used as an excuse to justify their claims. The other aspect under debate is that of working hours, since, as we have seen, they are fixed by agreement and the purpose does not change them. However, the workers in the situations in which they are required are going to contribute these overtime hours.

III. Full Implementation

As with corporate economic sustainability, the experts indicated that the results mentioned in the other two phases are improved in this one.

Environmental Sustainability

Finally, we come to the variables of environmental sustainability. There are two aspects that experts have pointed out in this area. The first is the growing legislation in this area, which in some cases means that the obligation does not allow the impact of the purpose to be seen. Some variables considered, such as toxic waste management or operations in environmentally sensitive locations have been considered as "not impacted" by the purpose for the reason that they are highly legislated. The second aspect is the need to include environmental considerations in the purpose for this impact to be significant. This second

consideration shows the relevance of including the environment as an important stakeholder for the company and of including it also in the strategic actions already mentioned.

II. Initial Implementation

In this aspect of sustainability, the results first appear when the purpose is initially being implemented. This is the case with a reduction in waste generated, a reduction in materials, energy and water used, and, in general, a reduction in emissions and effluents. It should be noted that the experts considered that most of these reductions occur when the purpose is fully implemented, but their first results appear at this stage.

Related to all these reductions in environmental impact we also have an improvement in the environmental impact of products, processes and services. Some of the experts considered that they were related to the variables in the previous paragraph, but independently they considered that there is an improvement in this phase.

II. Full Implementation

At the maturity level of full implementation is when the company should have already changed the transport it uses for both internal company mobility and logistics, if any. This can be with the hybridization or electrification of the fleet of personnel transport vehicles, but also with the optimization of logistic routes considering the emissions produced.

4 Conclusions

In the article we have tried to answer the question of how companies can implement the purpose to achieve corporate sustainability. We have done this with the described maturity model, which presents four aspects already mentioned in the literature: strategy, leadership, systems, and communication. However, it presents the actions with which these levers implement the purpose in a detail that is a novelty when it comes to understanding how implementation occurs. These actions also open the door to convert the maturity model into a diagnostic tool to place purpose-driven companies in one of the following maturity levels.

Another theoretical contribution is that purpose-driven companies have been related to the three parts of sustainability. Implementation, as argued in the results, leads to the emergence of sustainable behaviors and, these, to improvements in economic, social, and environmental sustainability. The specific variables on which it has an impact is also a contribution, as they can now be monitored and studied in depth to see the relationship that specific actions have with the results in these sustainability variables.

Finally, the maturity model also has practical implications. For example, companies can use it to better understand their own implementation process and, by comparing the actions established for the different models, decide what action to take next. It can also be used to facilitate the expected sustainability results. With further work, this maturity model could become both an implementation guide and a diagnostic tool for companies using the purpose to become more sustainable. Thus, the actions listed here can be evaluated according to their degree of implementation and their degree of impact. This will make it easier for companies to achieve the desired sustainability.

Moral Identity of Sustainable Entrepreneurs

Reeti Kulshrestha* and Arunaditya Sahay

Abstract

Worldwide, around 80% of the start-ups fall by the wayside. Sustainable entrepreneurs, who are few and far between, are individuals who develop sustainable ventures. The literature on sustainable entrepreneurship associates sustainable entrepreneurs with knowledge, skills, entrepreneurial self-efficacy, motivation, intention, values and attitudes, their business orientation, and moral cognition. The sustainability orientation of the venture places more emphasis on the moral aspect of the entrepreneur. Currently, there is a lack of understanding on how sustainable entrepreneurs navigate through their moral identity, how their moral identity gets formed and what are the antecedents of moral identity. In addition there is little knowledge on how moral identity influences their decision-making process and actions arising therefrom. There are still challenges in making meaning of sustainable entrepreneurship in theory and practice, and moral identity as such remains underexplored. It is said that morality plays an important role in decision making, ethical behavior and moral reasoning. Rooted in self, morality is self-organizing, self-reflective, and self-regulatory mechanism that regulates an individual's behaviour while facing moral issues. Adopting narrative inquiry, we delve into the moral identity of sustainable entrepreneurs to derive deeper meaning of their actions and practices. The research contributes to taking identity conversation in sustainable entrepreneurship research forward and bringing moral identity of sustainable entrepreneurs in focus.

Keywords- Moral Identity, Sustainable Entrepreneurship, sustainable entrepreneurs

1 Introduction

Traditionally, the purpose of entrepreneurship research was to generate economic value and make profits. Therefore, the focus was more on economic value creation measured by tangible outcomes like sales, profit or return on investment (ROI). With this emphasis on fulfilment of economic objective, environmental, and social issues were mostly avoided (Sarango-Lalangui et al., 2018). Gradually the field of entrepreneurship research opened up to other value creation opportunities like social, ecological, environmental and sustainability. As sustainable development has come about as a pressing issue affecting the world, sustainable entrepreneurship research is receiving increased attention (Teran-Yepez et al., 2019). This extension of knowledge to include other entrepreneurial activities acknowledged entrepreneurship as a solution to problems of economic social and environmental nature called as sustainable entrepreneurship (Munoz and Cohen, 2017). Yet another way to look at sustainable entrepreneurship is the process of opportunity recognition, creation, and exploitation to create economic, social, and ecological value (Belz & Binder, 2017; Eller et al., 2020). Since sustainable entrepreneurship addresses the environment more holistically, therefore, it holds great promise to contribute to sustainable development. It has the power to replace unsustainable products and services and transform markets and societies by providing socio-economic-environmental value that lead to sustainability (Esteves et al., 2021). But in order to create lasting

entrepreneur right from the start. While some research has been carried out on sustainability orientation and its interaction with entrepreneurial intention (Kuckertz & Wagner, 2010) and entrepreneurial action in venture creation (Muñoz & Dimov, 2015), little is known as to how entrepreneurial behaviours reinforces or acts counterproductive to sustainability orientation over a period of time. With focus now on sustainability and sustainable entrepreneurship, it is safe to assume that there will be a shift in the DNA of the entrepreneur including who they are, what actions they perform and why they are motivated to do what they do.

Entrepreneurs have been addressing sustainability related challenges for a while now. Thompson et al. (2011) distinguish between a social, environmental, and sustainable entrepreneurs. They mention that while the three are similar in their mission-driven strategies with the social entrepreneur inclined towards social, the environmental entrepreneur understandably towards environment related market failures, the sustainable entrepreneur strategizes with an objective to reap long-term benefits and achieve "triple bottom line" with all three, environmental, social, and economic benefits. In this manner, the sustainable entrepreneurs become agents of change committed to striking a balance between economic viability, social welfare, and environmental protection (Munoz and Dimov, 2015). Sustainable entrepreneurs, therefore, occupy the centre stage in achieving sustainable entrepreneurship to achieve and maintain a balance in triple bottom line goals within their businesses (Teran-Yepez et al., 2019). In the analysis carried out by Teran-Yepez et al. (2019), the findings reveal that entrepreneurs of the future need to be competent in sustainable entrepreneurship and possess different traits like systems thinking, foresight, strategic management skills (Ploum et al. 2018) while appreciating various norms and ready for action. Research suggest that when dealing with value-driven problems like sustainable development, individuals should possess values and norms that go beyond looking for tangible business outcomes for themselves (Teran-Yepez et al. (2019). Their boundaries need to reach out to include others. Scholars opine that amongst other competencies, the morality of the entrepreneur influences sustainable entrepreneurial process (Diepolder et al., 2021). Hardy and Carlo (2005) explain moral identity as "the degree to which being a moral individual is important to an individual's identity." But how this morality influences entrepreneurial behavior and venture creation process is still largely unknown. This creates knowledge gap in the sustainable entrepreneurship field (Musona et al.,2021). There is a lack of understanding on identity research in sustainable entrepreneurship. With little theoretical grounding on sustainable enterprise creation and entrepreneurial behaviour of the entrepreneurs is available, an identity perspective helps in explaining why sustainable entrepreneurs do what they do and how they do that (Musona et al., 2021).

Since a sustainable entrepreneur has to balance between three aspects, social; economic and environmental, it becomes even more interesting to see how the entrepreneur navigates his moral identity keeping the economic and environmental considerations in view. Exploring moral identity of sustainable entrepreneurs and how it influences their behaviour and actions shall bring out more insights into the field of sustainable entrepreneurship. Theoretical Background Sustainable Entrepreneurship Entrepreneurship is now increasingly being looked upon as a vehicle for creation environmental and social value (Musona et al., 2021) as well. Sustainable entrepreneurship includes entrepreneurial activities that create economic

and Vereeck (2004) define sustainable entrepreneurs as those who perform entrepreneurial activities and contribute to sustainable development by doing sustainable business. The three pillars of sustainable entrepreneurship namely social, environmental, and economic, refer to people, planet and profit. The word 'entrepreneur' means 'taking the initiative to bridge' and as such entrepreneurs bring together money, people, and ideas to establish value creating enterprises and networks (Schaltegger and Wagner, 2011). Sustainable entrepreneurs in addition also bridge the divide between environmental progress and market gains. Schaltegger and Wagner (2011) suggests that the core motivation of sustainable entrepreneurship is to contribute to solving societal and environmental problems through the realization of a successful business. Thus, sustainable entrepreneurship can be described as an innovative, market-oriented and personality driven form of creating economic and societal value (Schaltegger and Wagner, 2011). The objective of the sustainable entrepreneur is to make profit by providing sustainable value. This becomes even more pronounced in the post pandemic world. Mulqueen (2022) says that in the post pandemic reality, sustainable entrepreneurs face a complex ethical dilemma as they owe moral responsibility in their entrepreneurial practices and strategies. In sustainable entrepreneurship research, studies have examined and alternatively explored motivation, managing tensions between the three goals, and mobilization of resources (Musona et al., 2021). Our paper argues that it becomes imperative to explore identity of the sustainable entrepreneur as we make an attempt to understand their moral responsibilities, ethics, entrepreneurial actions, intentions, and behaviour, because it is the identity of the entrepreneur where the genesis of his being originates.

An individual holds multiple identities, and looked at from different vantage point, moral identity could have a personal identity aspect or a social identity aspect too. Entrepreneurs take up entrepreneurship for reasons of their own accord. Choosing to practice sustainable entrepreneurship, which is perhaps most complex of all, calls for a different personality traits, identity and moral obligation which is indicative of more of 'other oriented' behaviour than 'self-serving' interest. And when we wish to explore the identity of a sustainable entrepreneur, moral identity was found a good place to begin our research as it is scantily explored and promises rich insights.

2 Identity of a Sustainable Entrepreneur

The identity of sustainable entrepreneurs has various identity dimensions, including society, community as their frame of references, their social motivation, and their self-evaluation (Cesinger et al., 2021). Since sustainable entrepreneurs pursue the goal of generating profit and also creating social and/or ecological value, they often experience tension. In such a situation, they need a strong moral compass to remain true to their purpose and moral responsibility towards stakeholders. Fauchart and Gruber (2011) termed them as missionary founders who "believed that firms can be powerful agents of change in society and engaging in new enterprise can pursue their vision and advance particular causes, generally of a social or environmental nature."

We explore the moral identity in this paper as we believe that exploring moral identity helps in understanding the sustainable entrepreneur and the enterprise that he creates for generating social,

3 Moral identity

An individual has three primary identities, personal; social; and role identity. One's identity drives one's actions and behaviour. Research in the field of moral psychology suggests that for a better understanding of moral action, one has to consider the role of the self in morality, also called as "moral identity" (Jia and Krettenauer, 2017). Moral identity means how being moral is central to an individual's identity (Hardy and Carlo, 2011). Different scholars have researched moral identity and have expressed it through structure, mechanisms, and dynamics. According to Blasi's Self-Model of moral identity, when a person's identity is more centred on morality, there is an increased desire to live consistently with one's sense of self. Similar to this thought, Colby and Damon (1992) iterated that moral identity is the unison of the moral and self-systems. The more the unity between people's sense of morality and their personal goals, the more moral an individual will be. Frimer and Walker (2009) accounted this unity to the synergy between self interest and other-oriented interest. These are not seen as competing or opposite forces. The more the synergy, the more moral an individual will be. This communion of personal and moral goals becomes a powerful source of moral commitment and motivation for an individual which in our study is the sustainable entrepreneur (Frimer & Walker, 2009).

There is another explanation for moral identity given through schemas (Aquino, Freeman, Reed, Lim, & Felps, 2009). Schemas are mental representations of various dimensions to us, our relationships, and the experiences we have (Fiske, 2000). In our case, the moral identity of individual may include having morally important schemas available for information (Lapsley & Lasky, 2001). Individuals perceive moral schemas and their importance differently and give varying importance to morality with the overall sense of self (Aquino et al., 2009). Researchers opine that though in most cases, moral identity is something that is relatively stable across situations—like a personality trait (Moshman, 2005), but to some extent, the sense of moral identity is also constructed from one moment to another (Monin & Jordan 2009) and may be more or less active situationally (Aquino et al., 2009; Stets & Carter, 2006). Moral identity is an important source of moral motivation and can be a good predictor of moral actions and commitments (Damon & Hart, 1992) depending upon how moral identity is conceptualized (Blasi, 2004). A few studies examined and concluded that there are strong links between moral identity and action. This is the reason we decided to explore moral identity and how it contributes to becoming a sustainable entrepreneur.

There are discussions on social entrepreneurship which reveals an individual's morality (Paramita et al., 2022). This makes us assume that it applies to sustainable entrepreneurship as well. Studies indicate in the mentioned domain that the influence of moral identity is significant when individuals feel perceived proximity with the social problem they are trying to address. This study provides theoretical contributions to the literature on social entrepreneurship and ethics.

4 Moral identity in Entrepreneurship

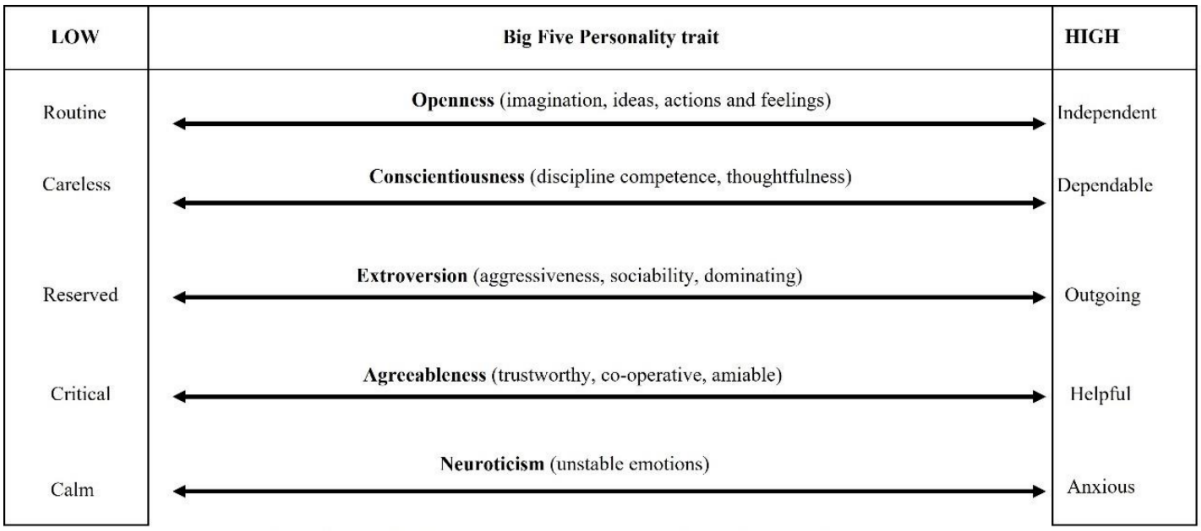
Aquino and Freeman (2017) opine that moral actions arise from moral identity as the entrepreneurs desires to have self-consistency (Blasi,1983). Towards this, Blasi (2005) proposed a three-component model of

defined moral identity as a self-schema which did not require a very long list of moral traits. They stated that stimulating a subset of moral traits would influence the entire network of associated traits. This meant that if an individual had some of the trait associations, the importance of moral identity for that individual and the centrality of moral identity could be assessed. They argued that moral identity is a selfregulatory mechanism that spurs an entrepreneur to make choices and take actions that show 'others' orientation which psychologists and moral philosophers consider important and defining feature of morality. Such mechanisms have its roots in the right and the wrong ethical behaviour (Aqiono and Reed 2002). Further to this, Kaptein (2019) shared that a leader, which in this case is a sustainable entrepreneur commits himself to a cause depending upon his moral identity and such leaders for whom moral identity is important, their actions are consistent with their moral identity and common understanding of being moral (Mayer et al. 2012). Therefore, we can say that for each individual, the centrality of moral identity is different in their overall self-concept (Aquino and Reed, 2002). This explains why entrepreneurs address ethical issues and utilize their resources to solve such problems (Eisenbeiss, 2012). This is true even more in the case of sustainable entrepreneurs who utilize their resources addressing social, environmental and economic objectives while being consistent with their moral identity and actions. Scholars have addressed the curiosity of whether moral identity create an intrinsic desire to do the right thing (Imbriaco,2017) and found that this can be explained by understanding it with the lens of identity theory (Stets and Carter, 2011) which states that an individual's actions are based upon their "identity meanings and interpretations" and that their actions and behaviour are largely regulated keeping that in mind.

A recent meta-analysis of antecedents of moral identity by Xiaofeng Xu and Ho Kwong Kwan (2021) revealed that gender, personality traits and organizational context (specifically, leadership style and ethical climate) are strongly associated with moral identity. In this study to explore moral identity, we have taken up the Big Five personality traits theory similar to that of Xu and Kwan (2021) .

5 Big Five theory of Personality traits

The biggest advantage of looking at moral identity with this theoretical lens is that it gives the freedom to explore a trait along a continuum rather than giving binary explanations. The model asserts that each personality trait is on a spectrum and an individual is ranked on a scale that swings between two extremes. Each personality trait mentioned in the model represents broad category of many personality-related terms. Each such trait covers multiple facets. We show the big five traits below along the spectrum.



Compiled by authors based on Big Five Personality Traits (Fiske, 1949).

It has been observed that people's scores of these Big Five traits remain generally stable for most of their life with only minor changes from one's childhood to becoming adult. However, in research conducted by Soto & John (2012), they showed that while agreeableness and conscientiousness increased with age, the gregariousness decreased with increase in assertiveness. Extraversion remained largely unchanged. They further showed that the openness to experiment and savour different experiences and being neurotic decreased as one grew older. Thus, some aspects changed significantly in the five traits, and some remained quite stable. This made exploring moral identity of sustainable entrepreneurs interesting as well as having potential for significant contribution towards moral identity literature.

6 McAdams and Pals (2006) Integrative Theory of Personality

McAdams and Pals (2006) articulated this five-point framework for describing an integrated personality. They described personality as (1) an individual's unique evolutionary and developing pattern of (2) dispositional traits, (3) characteristic adaptations, and (4) selfdefining life narratives, situated in (5) the culture and social context. McAdams and Pals (2006) opine that each human life is uniquely individual and variations on dispositional traits makes for the most stable and identifiable aspect of their psychological individuality (McCrae & Costa,1997). Other than the dispositional traits, the theory states that there are various adaptations that an individual undergoes (Emmons, 1986); these are socialcognitive (Mischel & Shoda, 1995), and developmental (Elder, 1995; Erikson, 1963) contextualized in time, place, and/or social role. In addition to this, each life has a uniquely individual personal narratives of their life stories and how they make meaning and construct identity (McAdams, 1985, 2006, 2008; McLean et al.,2007; Sarbin, 1986; Tomkins, 1987) and become liquidly modern selves (Bauman, 1996). This approach to understanding moral identity also says that context has a very significant role in development of personality. It shows a stronger impact on adaptations and life stories of people. The context provides with themes and plots for the psychosocial construction of identity. Morality influences our social lives (Mc Adams,2010) and the five basic traits identified by the researcher carry important moral meaning.

The most urgent need is to further probe the antecedents of moral identity from the perspectives of personality traits (Xiaofeng Xu and Ho Kwong Kwan, 2021). In light of the above literature, our research question is:

What are the antecedents of moral identity of sustainable entrepreneurs that define their moral self?

Methodology

The study applies a case study design with qualitative data collected through unstructured indepth interviews, carried out through narrative enquiry with enterprise founders. The data was complemented with secondary materials such as websites, online videos, news articles, and other media coverage. It was then analyzed in stages through thematic analysis. Since we wished to explore the moral identity of sustainable entrepreneurs, looking at the antecedents of moral identity was found a good place to begin with that was supported by literature to understand moral identity better and the dimensions that help forming moral identity. We take up the personality traits antecedents to probe moral identity of two sustainable entrepreneurs. A qualitative study requires rich data. We have chosen two entrepreneurs in order to carry out in-depth exploration with each one of them. The choice of these two entrepreneurs has been based on their suitability for the study. We wanted to study entrepreneurs who have been considerably for a long period of time into entrepreneurship. This would help us in seeing for any changes in their traits as time progressed and their identities evolved. Entrepreneurs who are into creating social value are better suited for exploring moral identity as they are 'others' oriented. We also take support of two frameworks that help explaining the personality traits, Fiske's (1949) Big Five theory as used by Xiaofeng Xu and Ho Kwong Kwan (2021) in their meta-analysis and McAdams' integrative theory (2009) that suggested future research to look at moral identity from the personality traits antecedent perspective. So, while the BigFive theory shall give us good grounds to carry out further analysis and research, the McAdams theory shall further enrich data analysis and interpretation bringing in deep insights. While Big Five reveals the traits that remain relatively stable over time, the McAdams theory captures evolution and temporality of moral identity. For the purpose of our study on moral identity, we have taken up two case studies of sustainable entrepreneurs who have been founders of the enterprise. We took Anshu Gupta of Goonj, and Parag Aggarwal of JanaJal.

7 Analysis and Findings

Anshu Gupta, Founder, Goonj

"*Goonj is an idea*", Anshu proudly says. Goonj is a social enterprise in India, which pioneered the idea of reusing cloth discarded by city households as a sustainable resource to generate work and empower marginalized people. We took up Goonj as a case study in this research to understand how a social enterprise uses an 'unsustainable' resource that ends up in landfills, into building sustainable societies, meaningful living, transitioning into a circular economy. By moving from 'Cloth for work' to 'Dignity for work', Goonj transforms the lives of socially and economically marginalized people by building trust, new opportunities, better living, and human dignity, through innovative use of discarded, under-utilized, and reusable urban

people in many ways, giving access to sanitation, health, education, cleaner environment, and dignified living. By ensuring that nothing goes waste, from cloth to other materials such as audio tapes or paper, Goonj becomes environmentally, socially, economically, and thus, sustainability-oriented enterprise. By carrying out unstructured interviews with the entrepreneur, we gathered narrative data to explore the moral identity of the entrepreneur in question. Our exploration was supported by looking at the personality traits elaborated by two theories, the Big Five traits and McAdams integrative theory.

We did a thematic analysis as described below:

Statements	**Big Five Traits**
"I did not like working for others and becoming an entrepreneur liberated me and gave me freedom" *"I had different experiences studying in all sorts of schools which were sometimes very good, sometimes not so good and even sometimes the ones which are now a part of Goonj's education vertical"*	Openness to experience
"My parents were very honest, and I am saying it repeatedly because it was and is a big part of my value system and where I come from"	Conscientiousness
"I have always been result-oriented since childhood, I wanted outdoor activity. Even today I find joy in activities like repairing of house or center even though I am no longer required there, but I take part. It gives me joy. I love the creative side of it, of building things. So, I would find this desk job dead and not what I wanted. I felt I was not made for this; this was not me. I felt my calling was different"	Extraversion
I ensured that all my employees and volunteers got their salaries and no worker associated with us during suffered. We did extensive work with migrant workers to help them in this hour of crisis. *"Such was my upbringing that there were times when being the only school in the area, the child who would bring milk to my house daily in the morning, would be studying with me in the class sometime later. Such was the beauty of our early days that we saw life as one and not different".*	Agreeableness
"We have not known any other way. Our house help was treated the same way we would be treated, offered food in the	
same utensils, and served hot food before they started their chores. Such was the way of life I had seen".	Neuroticism

Parag Agarwal, Founder, JanaJal

"Our mission is to make safe drinking water Available, Accessible and Affordable"- Parag Agarwal

JanaJal is a social enterprise that offers sustainable solutions through SMART technology where SMART represents Sustainable, Measurable, Agnostic, Resilient, and Timely. JanaJal envisions building India's first water-sharing economy and the largest decentralized water distribution network through installation and operation of water ATMs. The company is working to make safe drinking water available, accessible, and affordable to common man. They are trying to achieve this in a sustainable manner. The technology talks about being sustainable where JanaJal Hybrid Water ATMs maximize efficiency by utilizing solar energy and regular electricity minimizing down time due to power outages. JanaJal also encourages consumers to carry their own bottles and containers to collect water thereby reducing the generation of hazardous plastic waste. The enterprise, further, empowers and creates social entrepreneurs who serve communities with utmost dignity and pride. JanaJal 'Water on Wheels' (WOW) is an environment-friendly battery-operated vehicle that helps take safe water to households and contributes to the 'Right to Water' mission. It fulfils SDG goals with the objective of delivering water to peoples' doorstep allowing women increased economic productivity and children more time to focus on education. Parag is a sustainable entrepreneur who envisions a country where no one is denied the right to clean drinking water. He believes in democratization of water. Below are his narratives based on five personality traits.

Statements	Big Five Traits
"I always wanted to make a difference. I wanted to contribute, always wanted to overcome those gaps" *"I have always dreamt big and had been hearing comments of people all my life that I stretch beyond my means".* *"It served as the biggest motivator and the cause for fire to burn in my belly. I wanted to change the situation; I wanted to add to the fortunes of my family. I wanted to add to the financial and economic position of my family. My mother would often say that amongst all children on the maternal side, only I have inherited my grandfather's genes. Maybe I have always been wired like that".*	Openness to experience
"Born into a middle-class family, I have always had everything counted and measured, nothing was in excess". *"I have never cared for money, though I wanted to earn money to support my family, it held no value for me".* *"I had always drawn a line which I never crossed. As an entrepreneur you have to make a zone for yourself in which you will stay and operate. I made that for myself and never crossed those boundaries".*	Conscientiousness
"I had a risk appetite at all times. So, at the age of 21, I joined the stock markets in 1991"	Extraversion
"People were always most important to me"	Agreeableness
"You develop a mind which learns to overrule the heart and tells how you that it is ok till this point only, and if you go beyond this, it will hurt you, you may even spoil your relationships only to be blamed and end up defending yourself to people". *"I have two minds; one that applies to myself, and another to the world outside. In my internal silo, I have doubt not about myself but for the fact that am I doing the right thing…because I have a big responsibility.*	Neuroticism

8 Discussion

Based on the analysis, we can say that for Anshu Gupta is an independent openminded person who is imaginative, creative and has ideas that he wants to make them come true. He is also a very conscientious person as he shared in his narrative that their family values are based on honesty and integrity. That is how he has been brought up. He is high on extraversion as he shares that he was always interested in outdoor activity and an inside job made him feel chained. He also came out to be very agreeable as he was very empathetic towards his employees and to people he did not even know such as the migrant workers who were suffering due to extreme critical conditions of Covid19. The data shows him to be a calm and even-tempered person as he says that their house always treated everyone equally and that there was no distinction amongst people. This instilled in him a sense of equality and stability in his outlook towards life. He shares that his parents were very honest and ethical people, and that quality has been corner stone for him.

Parag, too, comes out as an openminded person high in ideas and imagination as he is always thinking beyond his means. Born in a middle-class family, he shares that he did not care for money for money's sake but only for the things he could do with it for others. For himself, money had no value. He stated that he had made boundaries for himself as an entrepreneur and always stayed within that zone. He is high on extraversion as he aggressively goes out and takes risks to move ahead in life. He is very agreeable as people were most important to him and would go to any extent to help others. Finally, he is found to be initially more emotional when he would trust others outrightly because of which he also got cheated and hurt by people. Gradually he became more careful with people and drew lines for himself so that he could stay away from such people and protect himself. He believes that as an entrepreneur, he has huge responsibility and so he always keeps checking upon himself whether he is doing right or wrong.

9 Conclusion

The study was carried out based on the Big Five personality traits by Fiske (1949) to know the antecedents of moral identity of the sustainable entrepreneurs. It also revealed how moral identity gets formed over a period of time and how important is the role of the context. We have yet to do the analysis based on the McAdam's (1996) integrative theory which will further enrich our understanding of moral identity. As future research avenue, exploring gender and organizational context can give significant peek into understanding moral identity from a different perspective.

Supporting sustainable transformations in corporations

Development of a strategic framework linking operational excellence with sustainability

Katharina E. Roche[1], Rupert J. Baumgartner[2]

[1]*Institute of Systems Sciences, Innovation and Sustainability Research, University of Graz, Merangasse 18/II, 8010 Graz, Austria, katharina.roche@uni-graz.at*

2. Abstract

Operations are critical for companies' efforts towards sustainable development, as they dictate which resources are used, the organisation's actual impact on environment and people as well as its economic performance. To achieve sustainable development, sustainable operations management is in search for models that integrate operational excellence with sustainability. This research aims to provide a comprehensive strategic framework integrating operational excellence and sustainability for enabling sustainable transformation of corporations. The research approach includes a literature review, providing a background on operational excellence, sustainability, and hoshin kanri. For both operations manage- ment as well as sustainability comprehensive frameworks were used as a foundation and adapted to- wards a potential framework for linking sustainability with operational excellence. As a management system for operations management hoshin kanri provides the main basis, which includes operational excellence principles. The Framework for Strategic Sustainable Development was combined with hoshin kanri, due to its practicality, its clearly defined sustainability principles, planning process as well as combination possibilities. The resulting framework illustrates how strategic sustainability goals can be aligned within a cooperation and in turn to achieve these in practice. This research contributes to- wards supporting corporations in their efforts to transform into sustainable businesses. The framework linking operational excellence with sustainability may serve as a theoretical base for future research that will include applying the framework to a company and further refining the framework.

Keywords: Operational excellence, hoshin kanri, sustainable operations management, Framework for Strategic Sustainable Development

1. Introduction

The increasing climate crises have massive implications for businesses as global markets are thoroughly interconnected (Drake and Spinler, 2013). Companies have not only been increasingly pressured by

are also increasingly seeking to achieve competitive advantage through corporate sustainability (RobecoSAM, 2014). A critical sustainability viewpoint is provided by operations management (OM). Operations dictate what the business does, i.e., which resources are used and, in turn, the organisation's actual impact on environment and people as well as its economic success (Drake and Spinler, 2013). Measures such as the triple bottom line (3BL), involve people, profit and the planet, and the goal of maintaining viable social as well as economic organisations. OM is increasingly connected to sustain- ability, and it now concerns both the operational drivers of profitability and their relationship to people and the planet (Kleindorfer et al., 2005). However, in research so far, it is not obvious how far social and environmental objectives are incorporated into various facets of OM (Gunasekaran and Subrama- nian, 2018). Sustainable OM is in search for models that integrate operational excellence with sustain- ability (Walker et al., 2014). Organisations are facing a substantial new challenge in terms of opera- tional sustainability (Bhandari et al., 2019; Ghadimi et al., 2019). The challenge for a company is to cope with business requirements in a short time, but at the same time to build up an appropriate culture, necessary leadership skills and operational excellence, all of which are necessary to be successful in the long term. However, there is often a disconnect between strategy and implementation, where day-to- day business has priority over the consideration of investing time and effort in planning in the long- term (Kudernatsch, 2019). Translating corporate strategy into operations strategy has been a key focus of OM for many decades. However, there still lacks a comprehensive framework that integrates the literature (Thürer et al., 2019). A management system, seen as to have potential for linking strategy and implementation in the long-term is hoshin kanri (HK), a specific form of policy deployment; among many other names in western countries (Jolayemi, 2008). Since the 1960s, HK has been put forward as a system for OM in Japan; it was invented by the Japanese company Bridgestone (Akao, 1991). By 1975, it had become widely adopted by other Japanese industries (Kondo, 1998). HK and versions thereof have been implemented by companies all around the world, such as Toyota, Hewlett-Packard, Nissan, Xerox, Texas Instruments, Tyco, IBM, Porter and Gamble and AT&T (Evans and Lindsay, 2005; Feurer et al., 1995; Witcher and Butterworth, 1999, 2000; Kudernatsch, 2019). HK is often asso- ciated with Total Quality Management (TQM) and Lean production (Lean or LP) and it is considered a typical system for OM (Karaszewski, 2010; Chiarini, 2013; Jolayemi, 2008). Due to a different cul- tural approach and problems related to translation from the Japanese, HK was not well known or used by Western companies until the 1990s (Tennant and Roberts, 2001). The TQM and Lean production movements brought HK to the attention of many worldwide companies that implement TQM and Lean. However, HK has not received as much attention as other management systems, such as the Balanced Score Card (BSC) (Witcher and Chau, 2007). As quality and sustainability are seen by the global com- munity in both business and customer markets as required characteristics, addressing operations and enhancing sustainability will become a necessary task for organisations (Piercy and Rich, 2015). The Framework for Strategic Sustainable Development (FSSD) is a meaningful strategic framework for

sustainability with potential to be combined with HK. It includes clearly defined sustainability princi- ples and planning process as well as combination possibilities with other management methods and tools (Broman and Robèrt 2017).

and operational excellence through HK. With regard to the research goal, the following research questions were formulated:

RQ 1 How can a framework for linking sustainability with operational excellence using hoshin kanri look like?

RQ 1.1 How can sustainability be linked to operational excellence through hoshin kanri?

RQ 1.2 How can operational excellence and sustainability be combined and applied through hoshin kanri towards a conceptual framework?

1.1 ***Theoretical***

Background

Operational

Excellence

Excellence tools are used by people in organisations as means to achieve results and requires people's motivation and participation, meaning strong leadership, top management commitment and fully in- volved and inspired employees (Shingo Institute, 2014). For a company to succeed in the long term, it needs to participate in a multitude of activities such as organisational excellence, product leadership, customer relationship management, to name a few (Found et al., 2018). Operational excellence has no commonly accepted definition (Found et al., 2018), however, definitions include many similar compo- nents. It can be defined as process efficiency and effectiveness with the systematic integration of an organisation's culture and its human resources (Bourke, 2014) and can be characterized as strategy that organisations use to provide quality, ease of purchase, price, and service in such a way that no other company in the sector or industry can match (Treacy and Wiersema, 2007). Sony (2019) stresses that via the so-called "4P's", people, partnership, process, and products, business or organisational excel- lence can be achieved. Organisational culture is considered as one of the most important critical success factors for the implementation and success of operational excellence programs; New techniques are often not embraced by an organisational culture, due to a lack in appropriate leadership or strategy (Carvalho et al., 2019). In any case, the results of operational excellence programs are influenced by the organisational culture and enablers (Carvalho et al., 2019). Enablers are current parameters and practices that utilize and help enterprises achieve agile capabilities (Bottani, 2009). Management ena- blers are among others, total quality management (TQM), Lean Management, total productive mainte- nance, kaizen (i.e., continuous development), supply chain management, among others (Carvalho et al., 2019). For an operational excellence program to be successful in the long-term, it is necessary for an organisation to be aware of the social, economic, and environmental demands of stakeholders and to transform these by reacting with suitable and innovative operational excellence solutions (Sony, 2019).

Hoshin kanri methods and models

HK or policy deployment prioritizes and focuses on a few selected goals that are important to achieve the

to achieve these goals are developed respectively. There are HK methods and models stated in most HK-related literature (da Silveira et al., 2017). Most importantly and dominantly are the Deming Cycle of Plan-Do-Check-Act (PDCA) or variations thereof, and the so-called “catchball” process. Oth- ers are the link between top management/business strategy and daily management/day-to-day business, as well as certain planning tools, the X-Matrix and A3 Report (Tennant and Roberts, 2001; Witcher, 2003; Jolayemi, 2008; da Silveira et al., 2017). The most recurring model within literature is the FAIR model (Witcher and Chau, 2007), illustrated in Figure 1. According to da Silveira et al. (2018) FAIR relates to the PDCA/Deming cycle, with the keywords focus (act), alignment (plan), integration (do), and review/responsiveness (check). The first step (focus/act) entails deciding on a few key strategic priorities for the coming year. These "hoshins," or strategic priorities, are significant adjustments re- quired to achieve the company's medium- and long-term goals. Increasing improvement and hoshin- related targets are expressed in a QCDE-scheme, where "quality" (Q) refers to customer goals, "cost"

(C) refers to efficiency and financial goals, "delivery" (D) refers to internal processes, logistics, and innovation goals, and "education" (E) refers to human resource development, morale, and safety goals (Witcher and Chau, 2007). The annual goals are then developed and deployed iteratively, both vertically and horizontally, within the organization with the so-called "catchball" process in the second step (alignment/plan) (da Silveira et al., 2018; Tennant and Roberts, 2001). The catchball mechanism starts with a carefully planned break through goal or hoshin and represents the operationalization of the strat- egy. Catchball consists of feedback and discussion about goals and the means to achieve these goals; the process is meant to close the “knowing-doing” gap (Pfeffer and Sutton, 2000). During this process, the goals and resource allocations can be affected (Tennant and Roberts, 2001). The agreed upon per- formance targets and action plans are integrated into the work routine in the third step (integration/do). The fourth and final element of the cycle (review / check) entails top management's annual diagnostic of how HK is being used to manage and achieve the company's strategic goals. The annual review gives valuable information that influences the choice of strategic breakthrough goals for the following annual cycle (da Silveira et al., 2018).

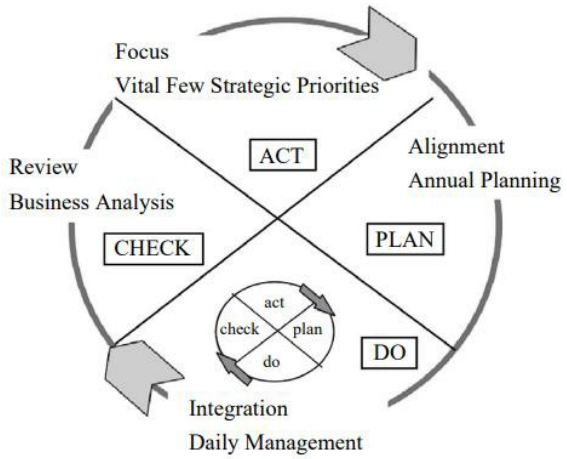

***Figure 1**: The "FAIR" model or PDCA cycle of HK (Witcher and Chau, 2007)*

The organisation's vision, strategy and breakthrough goals developed by the top management are cen- tral for the whole organisation and all its departments (Kudernatsch, 2019). However, important during the process of defining the annual goals, is the engagement with all levels ("cascading down") and goal transformation on all levels. This process illustrates the importance of feedback loops – the catchball process – within the organisation or business unit, to align the goals as effectively as possible by means of vertical (top-down and bottom-up) and horizontal (between departments) integration within the or- ganisation. The 7-step hoshin planning model by the GOAL/QPC Research Committee (1994) in Figure 2 depicts the stages within the hoshin planning process and is often referred to in academic literature (Jolayemi, 2008; Barnabé and Giorgino. 2017). Within this planning process model, the stages begin- ning from the organisational vision to the annual review are illustrated, including the catchball process during the deployment of objectives to departments (phase 4) and FAIR/PDCA cycles during the actual implementation and regular progress reviews. Depending on the annual reviews, the organisational vi- sion, 3-5-year plan, but most definitely the annual goals may be adjusted.

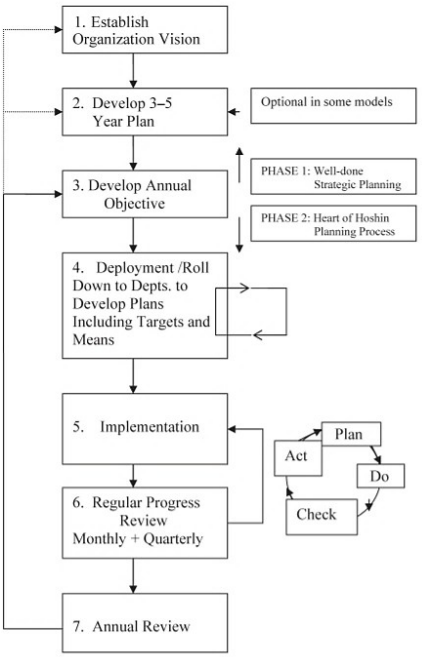

***Figure 2**: The hoshin planning context by the GOAL/QPC Research Committee (1994).*

The FSSD

The FSSD is a framework for strategic sustainable planning and aims to support organisations and institutions in their efforts to become sustainable. The FSSD provides organisations with a common language and a knowledge of the sustainability issue. It is founded on a sustainability vision, which is bounded by sustainability principles; starting from the vision, an organisation follows a backcasting approach (Robèrt 2009). The five levels of the FSSD by Robèrt et al. (2002) are (1) the system, which focuses on the ecosphere, (2) success, which defines the goal / outcome, i.e. the state sustainability within the ecosphere, (3) strategic guidelines, meaning the process to reach the outcome, (4) actions,i.e. concrete measures that comply with the principles for the process to reach a favourable outcome in the system, and (5) tools to monitor and audit the relevance of actions with reference to principles for the process and/or monitoring the status of the system itself, and impacts or reduced impacts, as a con- sequence of strategically planned societal actions. The FSSD principles by Broman and Robèrt (2017, p. 23) state that "in a sustainable society, nature is not subject to systematically increasing 1) concen- trations of substances extracted from the Earth's crust, 2) concentrations of substances produced by society, 3) degradation by physical means, and people are not subject to structural obstacles to 4) health, 5) influence, 6) competence, 7) impartiality, as well as 8) meaning-making". The operationalization of the FSSD is carried out through the so-called ABCD process. It is a four-stage iterative tool which integrates all the levels of FSSD (Broman and Robèrt 2017, p.7), including learning about the sustainability issue and – principles, and collectively developing the organisation's vision (A), a baseline as- sessment of the actual state of the organisation's sustainability (B), co-creating possible solutions and actions to achieve the organisation's vision (C), and deciding on which solutions are viable and feasible (D). Here, the solutions are prioritized, whether they are likely to help achieve the organisation's sus- tainability-framed vision (Broman and Robèrt 2017).

2. Methods

The first step is to gain a comprehensive background on operational excellence, sustainability, and HK. For this, an explorative literature review to operational excellence, HK (integrating TQM and LP) and sustainability is performed. In a second step, a conceptual framework is proposed. From this basis of this theoretical paper, future steps will include expert feedback, a case study approach, and iterative refinement processes.

2.1. Literature review

Data were collected from an electronic database search for the literature review. As proposed by Web- ster and Watson (2002), the search was undertaken by topic rather than by (top) journal to include 'all' published publications in this field. The search terms used in searching the scientific databases were divided into three theme groups focusing on operational excellence, (corporate) sustainability and hoshin

kanri. The key words in each group were associated with the Boolean OR operator to create a search string for the respective group. Also, the group search strings were associated with the Boolean AND operator to develop combined search strings (Vrontis and Christofi, 2019). Further keywords used were policy deployment, and strategy deployment (for hoshin kanri), sustainab*, operations manage- ment. Primary data bases that were used were Web of Science and Scopus; Google Scholar was added for supplementary reasons, as few search results were achieved when combining all three keywords (sustainab*, operational excellence, and hoshin kanri). The data from Google Scholar were extracted with Harzing's 'Publish or Perish' software (v7.33.3388.7819) in September 2021 and repeated in No- vember 2021 (version 8.0.3590.7978). Not only academic journals were included, but also conference proceedings and other grey literature by reputed publishers that may help overcome publication biases in literature (Hopewell et al., 2005). To achieve meaningful results, the timeframe as well as geograph- ical context were kept non-specific. The initial sample of possibly relevant articles were subject to ad- ditional evaluation based on different criteria. First, the search did not focus on publications in peer- reviewed academic journals with full texts. Thus, non-academic articles, such as book chapters, edito- rials, conference papers, extended abstracts, book reviews were included. Second, articles available in English were included and others excluded. This decision should bring focus on the common scientific knowledge base represented by most scientific journals and is employed by other researchers as well (e.g., Crossan and Apaydin, 2010; Vrontis and Christofi, 2019). Further filter steps after the removal of duplicates included title and abstract screening. The remaining publications were then subject to a full-text screening. The dataset after screening includes 90 publications. (The total number of publications for analysis is subject to change, due to additions of further filter steps (e.g, according to the number of citations) as well as of further identified references.) Journals, conference proceedings, books/chapters, and working papers are among the publishing types extracted.

2.2. Framework development

Based on the information retrieved as well as the findings on previously depicted frameworks, namely the Framework for Strategic Sustainable Development (FSSD) and HK, a conceptual framework was developed. HK as a management system links strategy and implementation in the long-term. HK can be viewed as key to achieving superior organisational learning and that it can be employed "to manage about anything that moves" (Jackson, 2006, p. XII), for example to integrate value stream activities within a single plant, office, hospital, etc. or integrating a total value stream involving multiple suppli- ers. While HK was still relatively unknown years ago, more and more western companies, especially in the USA and Europe, are introducing HK, mostly under the term 'policy deployment' (Kudernatsch, 2019). The FSSD was developed through several iterations within a 25-year-long learning process that involved scientists and practitioners alike (Broman and Robèrt, 2017). The FSSD has been applied in various companies, e.g., IKEA, Interface, Electrolux, but also to municipalities and for educational guidance. Through years of practice, there have been experienced benefits through applying the FSSD mentioned in a myriad of cases (Broman and Robèrt, 2017). Due to its practicality, its clearly defined sustainability principles, and planning process as well as combination possibilities with other manage- ment methods and tools, the

FSSD was chosen as the framework for sustainability to be combined with HK.

3. Results and Discussion

The results are structured two-fold: in (1) the key insights from the literature review, and (2) conceptual framework development.

3.1. Literature review

Operational Excellence, Sustainability and HK

According to Sony (2019), for an operational excellence program to be sustainable, the three main conceptual viewpoints of social, economic, and environmental factors should be imbedded in the organisational culture. An organisation's agility also plays a key role for the sustainability of operational excellence programs (Sony, 2019). Agility can be defined as an organisation's ability to identify changes in its business environment and provide its stakeholders with focused and rapid responses by rearrang- ing its resources, processes, and strategies (Mathiyakalan et al., 2005; Carvalho et al., 2019). Analysed influencing factors from literature for the successful implementation of operational excellence as well

as sustainability are leadership and strongly engaged top management (da Silveira et al., 2017; Morsing and Oswald, 2009; Shingo Institute, 2014); organisational culture; organisational agility (Sony, 2019; Carvalho et al., 2019); organisational learning and continuous improvement (Souza and Alves, 2018; Sawhney et al., 2020), organisational capabilities (Thürer, et al., 2019; da Silveira et al., 2018), as well as employee involvement and communication. However, in research the mechanisms associated with these factors are seldom addressed – for example, how management exercises leadership and communi- cates. The HK methodology is one of those mechanisms which evolved alongside TQM and Lean (Nicholas, 2016). HK may act as enabler for enterprises to achieve agile capabilities (Jackson, 2006; Carvalho, 2019). HK may provide a basis for implementing sustainability strategy within an organisa- tion and fill gaps between sustainability strategy and its actual implementation in day-to-day business. Attributes of operational excellence involve dynamic capabilities, alignment and synchronization of resources, continuous improvement, efficiency, effectiveness, and an enabler-focus (Jaeger and Matyas, 2016).

TQM, Lean and HK

TQM and Lean are both management approaches associated with business and operational excellence and often researched with regards to corporate sustainability. One of the goals of lean operations is to use fewer resources to generate the same outcome. As less materials are used in production, and quality improvements reduce rework, scrap, power/water consumption, and pollution costs, environmental ben- efits are observed (e.g., Rothenberg et al., 2001). However, lean operations could be criticized for fo- cusing on resource efficiency and issues that are not aligned with addressing wider scale problems and sustainability benefits lean operations can affect have generally been mostly limited to environmental performance (Mollenkopf et al., 2010; Miller and Sardner, 2012; Prasad and Sutharasan, 2012). A re- curring issue in sustainable

operations literature is the focus on environmental aspects (Walker et al., 2014). There is a great demand for sustainability models that consider economic, social, and environ- mental perspectives, also within the implementation of management systems and lean manufacturing systems (Souza and Alves, 2018). The aims of Six Sigma are to improve process performance and achieve high levels of quality by investigating and eliminating the root causes of defects and minimizing process and product variability (Cherrafi et al., 2016). Research attention has increased on combining lean, six sigma and sustainability. Lean Six Sigma is the combination of lean and Six Sigma philoso- phies (Sheridan, 2000), which aims to overcome the shortcomings of both methodologies as well as to increase potential improvement (Bhuiyan and Baghel, 2005; Snee, 2010). However, organisations are facing difficulties in managing the complexity of integration process and high amount of human and financial resources (Nunhes et al., 2017) and the necessary tools, to integrate such systems into an organization (Souza et al., 2018). Research by Souza and Alves (2018) introduces the Lean-Integrated Management System for Sustainability Improvement, which is based on the rational use of resources and energy while engaging and empowering people. In their research, many correlations and synergies exist between Corporate Sustainability standards and requirements (ISO 9001:2015, ISO 14001:2015, OHSAS 18001:2007, ISO 26000:2010) and HK and/or qualities associated with HK (such as Kaizen and Kanban). The survey by Nicholas (2016) finds HK in theory potentially provides much of what the published research says is important to lean production success.

Tools for strategy formulation and deployment – the Balanced Scorecard and HK

HK, the BSC, and other operational excellence frameworks, provide a structure and a set of procedures to align strategy throughout the company and to measure and manage progress towards corporate strat- egy achievement (da Silveira et al., 2017). The BSC, for example, is strong in defining what should be done, but it has little to say about how this should be done (Witcher, 2013). The key to linking strategy to action is therefore not the balanced scorecard itself, but the underlying procedures that make it func- tion (Witcher and Chau, 2007). HK emphasizes singular techniques such as feedback cycles between different levels of an organisation, i.e., the before described catchball process, on what should and what can be achieved and, above all, how it can be achieved (da Silveira et al., 2018). HK proposes the catchball process for better sharing the strategies and involving all employees. By contrast, the Balanced Scorecard (BSC) system introduced by Kaplan and Norton (1992) is based on a more top-down ap- proach. Within the BSC, starting at a corporate level, senior managers set strategies for the market and deploy these strategies for the different business units and levels of the organisation (Chiarini, 2016). The Sustainability Balanced Scorecard (SBSC) developed by Figge et al. (2002) includes environmen- tal and social aspects within the BSC; research in this field considering HK have not been developed thus far. However, the SBSC subsumes sustainability within the goals of companies and does not link sustainability objectives to economic performance which may constrain companies the kind of deep transformation and radical shift necessary to contribute towards a more sustainable future. From a social and economic perspective, HK enhances an integrated workplace, but also drives forward company performance. At the same time, HK as a TQM/Lean system shows environmental benefits, due to saving resources in production and through quality

improvements (Piercy and Rich, 2015). In Table 1, a sum- mary of the attributes of operational excellence, associated management systems (TQM, Lean, Six Sigma) and key tools (BSC, HK) as well as (potentially) integrated sustainability aspects are depicted.

Table 1. *Selected management systems and tools integrating OE attributes and sustainability aspects.*

	Attributes of operational excellence						**ed Sustainability Aspects**

3.2. Framework combining sustainability with operational excellence

A conceptual framework for linking sustainability with operations in Figure 3 combines the deployment process of goals (Barnabè and Giorgino, 2017) with the FAIR-model (Witcher and Chau, 2007) as well as includes the FSSD levels and principles (Broman and Robèrt, 2017); additional questions were added for clarification and guidance purposes (Kudernatsch, 2019). Sustainability objectives can be included within the targets, based on the vision, mission, values as well as the business model of an organisation (core capabilities and competencies) (Figge and Schaltegger, 2002). The framework provides an over- view on how sustainability objectives can be aligned throughout an entire organisation.

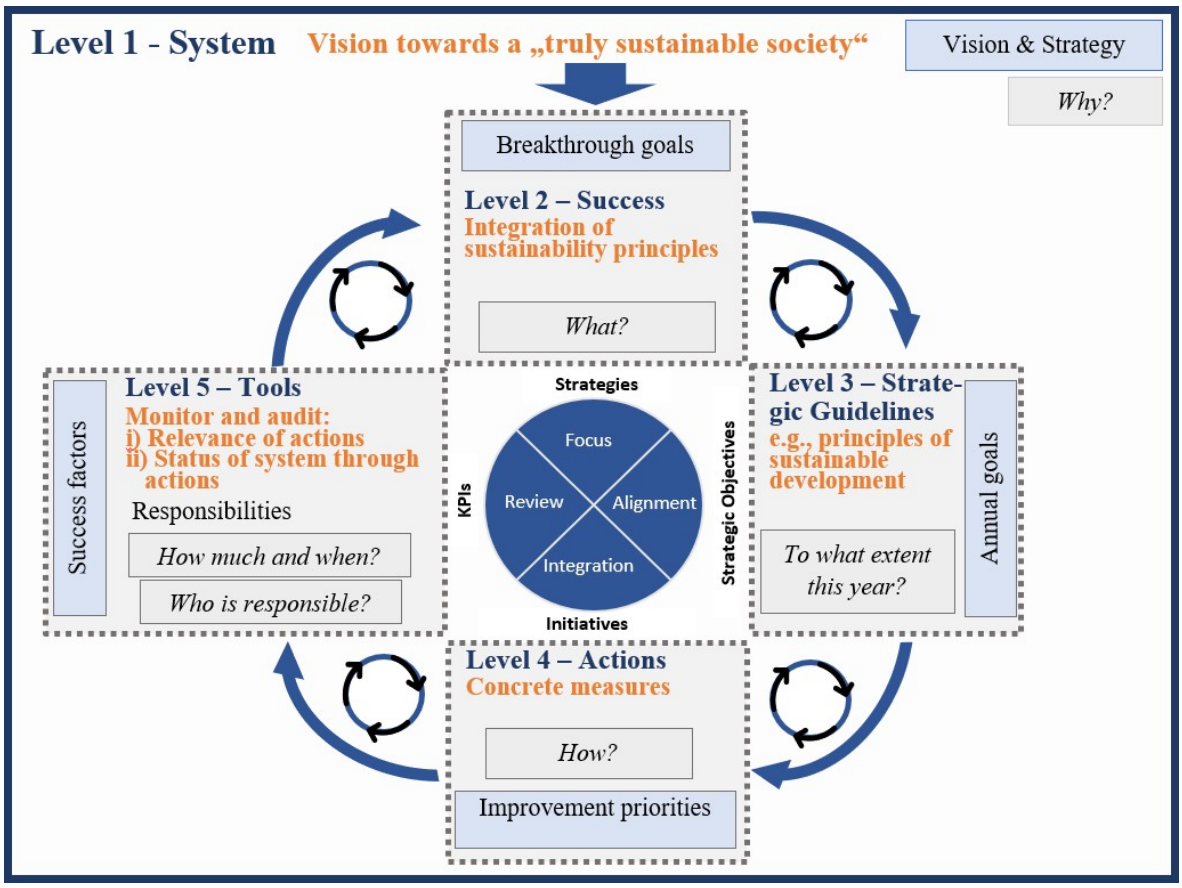

Figure 3. *Framework for Linking Sustainability in Strategy with Operations. Structure based on Barnabè and Giorgino, 2017; FAIR based on Witcher and Chau, 2007; Levels and sustainability aspects based on Broman and Robèrt, 2017)*

In Level 1, the system level (Why?), focuses on the ecosphere and should be incorporated in the vision as a "truly sustainable society". Here lies the foundation of the purpose of an organisation, and its con- tribution towards sustainability. In the second level, success (What?), the goal or outcome is defined, i.e., the state of sustainability within the ecosphere; here the sustainability principles from the FSSD can be integrated. The framework includes the breakthrough goals (3-5) of a certain company or busi- ness unit (i.e., Strategies), divided in a scheme of quality, cost, delivery, and education objectives (Kudernatsch, 2019). Sustainability principles can be aligned with the general goals or be formulated as stand-alone sustainability objectives that are accordance with the sustainability principles of the FSSD. In the third level, that of strategic guidelines (What and to what extent this year?), which con- stitutes the process to reach the desired outcome, the principles of sustainable development are inte- grated. In the framework, the strategic guidelines can be included within the annual goals (i.e., strategic objectives). Level 4 (How?), actions, i.e., concrete measures that comply with the principles for the process to reach a favourable outcome in the system. Within the framework these measures will be integrated in the improvement priorities section (i.e., initiatives/tactics). Level 5 (How much and when?) focuses on tools to monitor and audit (i) the relevance of actions with reference to principles

for the process and/or monitoring (ii) the status of the system itself, and impacts or reduced impacts, due strategically planned societal actions (Broman and Robèrt, 2017). In the framework, this level aligns with success factors (i.e., KPIs). Within the actions, accountability / responsibility concerning the different goals and tasks defined (i.e., Who is responsible?). The catchball process is highlighted throughout all levels, as the breakthrough goals integrating sustainability principles should be redefined through the alignment with the annual goals, the setting of concrete measures as well as the definition of tools and success factors.

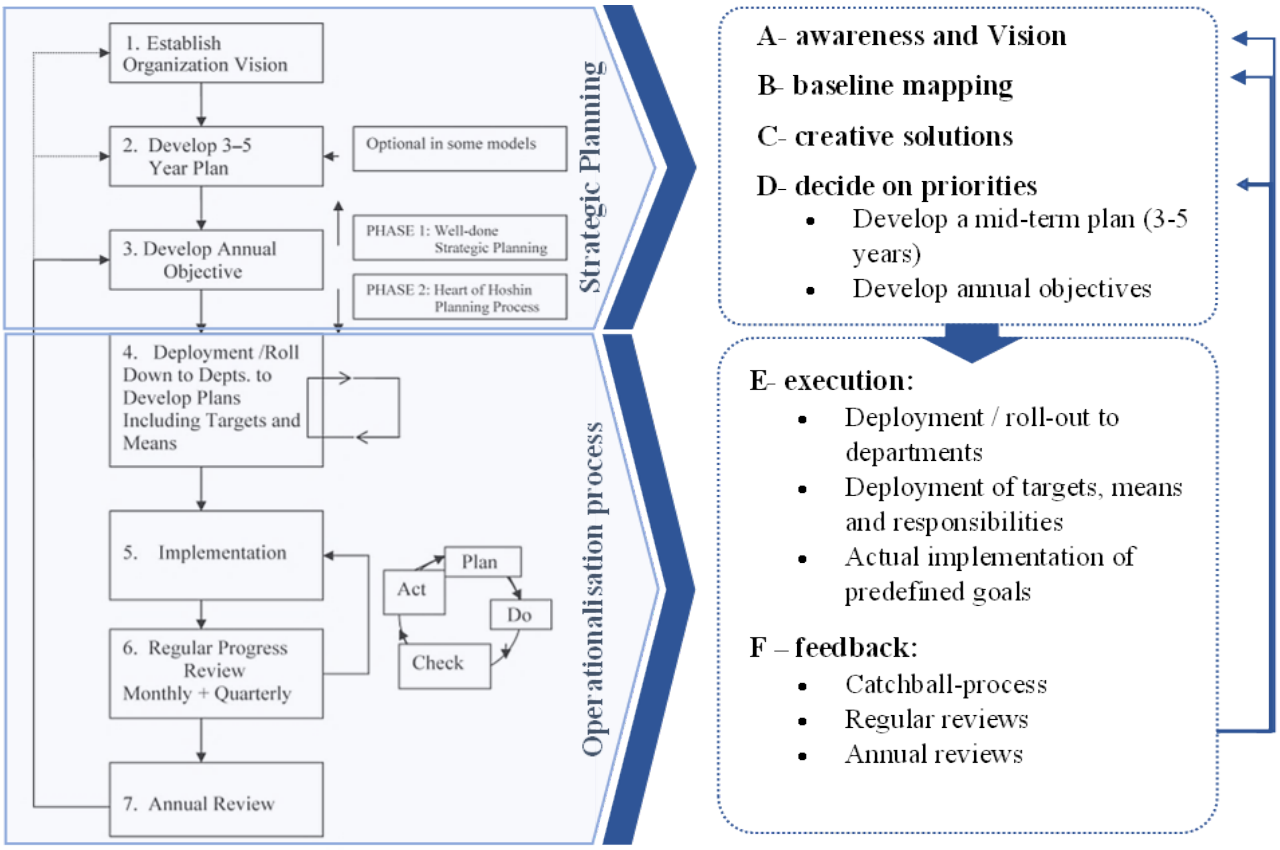

***Figure 4**: The proposed ABCDEF-process framework (adapted ABCD planning method (Broman and Robèrt, 2017) through alignment with the hoshin planning context by the GOAL/QPC Research Com- mittee (1994)).*

An implementation process framework shown in Figure 4 was derived by combining both the hoshin planning process as well as the FSSD's ABCD strategic planning method. Here, the seven steps of the hoshin planning context presented in GOAL/QPC Research Committee (1994) was used as a basis to provide an adapted ABCD-method from the Framework for Strategic Sustainable Development by Bro- man and Robèrt (2017). The FSSD strategic planning method was complemented with additional exe- cution and feedback phases, proposing an ABCDEF-method towards deploying an FSSD. Steps 1-3 (A, B, C, and D) include the classic strategic planning process for sustainable development, provided with the FSSD. However, these visions and strategic goals still need to be implemented/deployed within all

levels of the organisation. This process should be supported through stages execution and feedback. Steps 4-7 (E and F) focus on the (successful) deployment of the defined strategic goals. The previously proposed strategy deployment framework acts as a guide to supporting goal alignment throughout the whole organisation, namely the breakdown of strategic goals on all levels to their measurement on operations level (up to the definition of KPIs).

4. Conclusions

The results obtained should be able to give insights about sustainable operational excellence, relation- ship between operational excellence, HK and sustainability and fill gaps in literature topics, especially concerning frameworks for sustainable operational excellence. With this research, contributions to- wards the identification of possible links between operational excellence and sustainability, as well as challenges and benefits for implementing HK should be achieved. As a strategy deployment framework, HK is promising and has already shown many positive results when properly implemented. HK has the potential of linking strategy with operations, hence linking sustainability on a strategic level to its im- plementation in daily management. The developed framework should prove exactly that – a framework combining sustainability and operational excellence towards an integrated framework through HK. The present study serves as a theoretical foundation for further research process. For validation purposes, empirical data will be collected from practitioners and experts in the field of operations management. Another research opportunity arises by then applying the theoretical findings of a further validated framework in a later stage to a case study. These would help discover further insights, limitations and help develop the framework further. In this context it would be of interest to analyse the influencing factors for implementation, such as the level of maturity and size of a company, the organisational structure and culture, pre-existing lean production, or other management systems as well as tools for strategic planning and implementation. Limitations of this study are, that the literature review and re- sulting framework provide a theoretical finding. Another limitation is the strong focus on HK, as it is not as well known in western countries as in Japan; as a result, it may be difficult to implement due to cultural differences. However, as stated within the study, examples of companies exist that prove oth- erwise and which have integrated and rearranged HK to fit the companies own organisational culture (e.g., Texas instruments, IBM). The sustainability framework used itself, the FSSD, may also show potential for improvement; however, it provides a holistic yet practical framework that has proven to be useful in a myriad of cases and has been developed throughout decades of practical experience and research efforts.

Breaking the glass ceiling for women: Is it the recipe for sustainability management in companies?

This research focuses on analyzing the characteristics and capacities linked to sustainability management and the dominant women profiles in areas of sustainability.

1 Research Goal & Hypotheses

Research Goal

- Identify the characteristics of women's involvement in corporate sustainability management

Hypotheses

- **H1:** Women have greater participation in sustainability management than men
- **H2:** Sustainability management positions are related to professional vocation and "soft" skills.

2 Research question

Which is the role of sustainability managers, especially women in these positions that lead to social and environmental sustainability in companies?

3 Method

Census

- 300 persons among managers, bosses, coordinators, and sustainability analysts.
- Reference method and snowball technique
- People were contacted reference method or snowball technique

Survey

- Questionnaire: 35 questions (16 based on a Likert scale)
- Qualtrics (Online survey services)
- Response rate: 18.6%

4 Findings

Sociodemographic characteristics:

44 respondents

- 54% women & 46% men
- 57% live as a couple
- 71% postgraduate studies
- Wages: >50% 1200 € , 14% between 2000 and 4000 €, and 11% more than 4000 € per month

H1: Confirmed

Women occupy 72% of middle and high positions in sustainability management.

Management focus on:

- Leading the sustainability team
- Designing, coordinating and executing the environmental and social management strategy

H2: Confirmed

80% spend a large part of their time leading: the work team dedicated to sustainability and communication with the managers of each company area. In addition, 77% spend part of their time designing the environmental management strategy, and 66% spend part of their time designing the social management strategy.

5 Conclusions

- Sustainability managers lead to sustainability in a balanced way in social and environmental matters at the same time, which is why they require resources and capacities for both areas of work.
- 80% affirm that one of its main functions is the training and awareness of the staff. However, 75% of sustainability leaders say they coordinate and execute sustainability strategies themselves, and only 25% have more room to delegate. This is contradictory because more than 75% have a role related to senior management, which suggests that they have small work teams. In addition, more than half must manage to obtain environmental and social certification.

- The participants, in general, consider the companies to which they belong to be diverse and equitable and believe that their promotions are due to merit systems and not gender. However, this may indicate a limitation in the sample since they are all companies with sustainability areas.

CSR disclosure in the automative industry

STUDY

How the automative industry disclosure social responsibility issues to their stakeholders?

WHY THIS SUBJECT?

- 4 million direct jobs (Papatheodorou & Harris, 2007);
- Contributes to traffic jams on roads (Meister, 2019);
- Increased emissions of polluting gases into the atmosphere (Meister, 2019);
- Social status symbol (vintage automobiles) (Meister, 2019);
- Current and present problem around the world.

TEORY

Social Responsibility – companies must have social concerns

Stakeholders – individual or group of individuals who affect or are affected by the company (Freeman, 2010)

Legitimacy – desirable actions within a society (Suchman, 1995)

METHODOLOGY

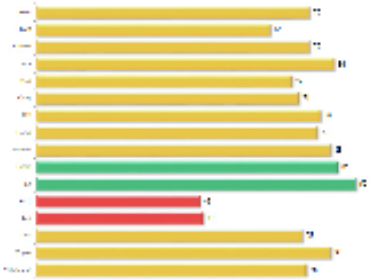
- Qualitative data
- 16 sustainability reports
- Fiscal year 2019
- Car manufacturing companies
- Likert scale with 5 levels
- Quantitative data analysis

RESULTS

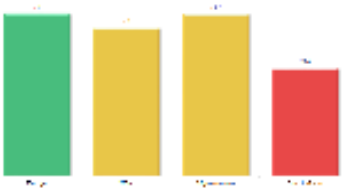
- 14 of 16 companies use GRI and 14 of 16 companies use ISO
- 12 of 16 companies refere SDG
- Philanthropy theme was the most mentioned followed by water consumption. On the other hand, the topics of toxicity to the population and land use are the least explored topics.

Graph 1 – Frequency of SDGs in sustainability reports.

Graph 2 – Disclosure of Social Responsibility by theme.



Graph 3 – Disclosure of Social Responsibility by company.



Graph 4 – Disclosure of Social Responsibility by region of the globe.

CONCLUSION

Companies use sustainability reports as a form of communication and as a form of publicity in order to legitimize their activity with society.

Stakeholders are present in the reports, especially the dialogues between them and the company.

The reports are not uniform, which makes their analysis and comparison difficult.

Finally, the existence of reports is a step towards sustainable development, however it is necessary to bear in mind that there are differences between what is disclosed and what is actually done by companies.

Voluntary Sustainability Standards for Corporate Social Responsibility

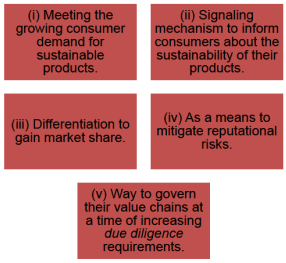
Introduction

Increasingly, social and environmental issues and the demands of consumers and large global businesses for products that present a better environmental performance throughout their life cycle have demanded from companies more commitment and responsibility to minimize the impacts of their activities. These pressures coming from the market and consumers have led to an increase in the demand for sustainable certification of processes and products, making the Voluntary Sustainability Standards (VSS) a present issue in business and Global Value Chains (GVCs).

The United Nations Forum on Sustainability Standards (UNFSS) conceptualizes the VSS as special rules that ensure that the products we buy do not harm the environment and the people who make them (UNFSS, 2018).

The adoption of voluntary standards also provides mechanisms to face the external forces experienced by companies in increasingly global environments that comply with the principles of Corporate Social Responsibility (CSR).

For Galati et al. (2017) such mechanisms correspond to:



Objective: to link the Voluntary Sustainability Standards to Corporate Social Responsibility, making an overview, through a literature review, of standards, global trade, and CSR, bringing contributions and challenges on these very current issues and present in the global market.

Voluntary Sustainability Standards (VSS)

The Voluntary Sustainability Standards (VSS) have emerged as global regulatory mechanisms to address sustainability, quality, health, and safety in organizations and their value chains (Büthe; Mattli, 2011). Consequently, private actors such as Non-Governmental Organizations (NGOs), industry associations, and transnational bodies have emerged and developed rules to govern various management practices (Castka; Corbett, 2015).

Main Voluntary Sustainability Standards and applications.

VSS	SECTOR/ PRODUCT
4C	Coffee
Better Cotton Initiative	Cotton
BONSUCRO	Sugarcane
Cotton Made in Africa	Cotton
Fair Trade Certified	Agricultural production
Forest Stewardship Council	Forest
Ethical Trading Initiative - ETI	Labor practices
GLOBAL GAP	agricultural production
Organics International Standard - IFOAM	organic crop production
Program for the Endorsement of Forest Certification - PEFC	Forest
ProTerra Foundation	agricultural production and feed
Rainforest Alliance *	Forest
Round table on Sustainable Palm Oil - RSPO	Palm Oil
Round Table on Responsible Soy - RTRS	Soy
Travelife Award of Excellence	Tourism
USDA National Organic Program - NOP	Organic Products
Union for Ethical BioCommerce - UEBT	Agriculture, Floriculture, Horticulture

Source: ITC/Standards Map (2021).

Corporate Social Responsibility (CSR)

Studies on the topic of Corporate Social Responsibility (CSR) gained importance and greater popularity internationally during the 1970s and 1980s, but their origin dates back to the late nineteenth century due to pressure from society towards the industries with the Industrial Revolution.

Dahlsrud (2008) states that there is no universal understanding of the meaning of CSR. Benabou and Tirole (2010) say that CSR definitions emphasize that companies sacrifice profits for the social interest.

However, when the company sets a standard to achieve only limited corporate goals, such as improving its image, no benefit can be expected.

VSS Contributions to CSR

- Boost workers' earnings (Bennett, 2018);
- In the CSR strategies, they may be stronger in quality control, health, safety, and environmental management than in employee compensation and benefits (Kortelainen, 2008);
- International Labor Organization (ILO) Standards focus on horizontal wage equity, for example, equal pay for equal work (Bennett, 2018);
- Improving rural livelihoods (Ting et al., 2016).

Main challenges VSS and CSR

- VSS can be problematic when addressing areas that are already covered by technical regulations.
- The real effect of these norms on international trade and, especially, on exports from developing countries.
- The rules or international agreements that can be applied to the frame or provide incentives and disincentives for these standards.
- The growing number of VSS available on the market.
- Need to have adequate information about VSS and its effects on the national market
- Lack of transparency in the disclosure of data.

Conclusion

The new paradigm of corporate social responsibility and accountability needs to be actively supported by changes in the governance structure to provide fair competition in the global economy.

Adopting sustainable certification, producing sustainably, and communicating all of this to customers is a strategy to improve the corporate image, differentiate products, add value, and position or reposition itself in the market.

There are many similarities in the characteristics of the VSS and CSR themes: multidimensional and multidisciplinary nature; qualitative nature of most structures; voluntary nature; the presence of themes related to the dimensions of sustainability and concepts related to sustainable development. Furthermore, both themes are constantly changing both in nomenclature and in their concept.

It is concluded that the certifications based on internationally recognized standards and CSR concepts are tools that can chart paths to achieve sustainable development.

Co-designing Measurement and Reduction of Food Loss and Waste: A case study of developing and refining tools

Associate Professor Simon Lockrey, Mr Allister Hill, Ms Lauren Rigbye, Ms Margaux Monnier-Penny, Associate Professor Karli Verghese

RMIT University, Melbourne, Australia

Abstract

Food is a fundamental tenent related to human rights, as it sustains people. Food also helps shape economic, political, performative, and social institutions i.e. we 'mingle' when we eat. In short, food is fundamental to humanity. As such, food loss and waste has been framed globally as a multibillion-dollar issue, adding to food insecurity and damaging attempts to curtail widespread hunger, not to mention the vast associated environmental impacts. Remedying food loss and waste requires organizations to accurately quantify their waste issue. Accurate estimates or measurements of the quantity of food loss and waste produced, and related costs, are necessary if society is to transform food systems to be more sustainable. It is hard to fix what you cannot measure.

This paper documents the development of a tool that assists organizations to measure and act upon food loss and waste. The tool was co-designed with industry, a creative participatory approach, to; be user friendly, and fit with business systems and workflows; and align to relevant data. Our primary contribution is detailing the co-design approach taken during product development, to inform how such tools may be developed or enhanced in the future. We achieve this research by analyzing four case studies of stakeholders who trialed the tool. Both small and large companies participated, for a spread of organizational contexts from which to provide data on tool strengths and areas for change. We assessed what made sense to participants within the initial tool prototype, and what could enhance the functionally of the tool for users. This was loosely based on an action research approach. By taking this approach we grounded our research in a real tool development project, to assess methods for food loss and waste measurement, novel user interfaces, and business readiness of the tool i.e. synergies with business data, systems and workflows.

Results show important features of the tool tested were; alignment to global standards for trust and data integrity (i.e. the global Food Loss and Waste Standard, or ISO14051 for mass cost flow accounting); simple data entry, or indeed data entry automation; graphical and tabulated data on both benchmarked and prospective scenarios; hot spot measures and visualizations of the mass and costs of waste at various supply chain stages; modularity with business systems; mapping effects of change, such as comparing future scenarios to benchmarks; and being able to download results. Improvements identified during the co-design process included; allowing automatic saving of models to avoid data loss; better guidance/ nudging of data/ work flows; and the ability to bring outputs from a life cycle stage across as an input to the next stage.

We conclude by discussing areas for future research, with a focus on implications for teams developing or improving food loss and waste tools. This has implications for organizations in how they may co-design related solutions to reduce food waste across disciplinary bounds, creatively, a pursuit which is central to United Nations Sustainable Development Goal 12, Target 12.3, of reducing food loss and waste by half by 2030.

Connect the Dots by Digits: How can complementors link themselves to existing business models in sustainable ecosystems?

Professor Pejvak Oghazi[1], Dr Maximilian Palmié[2], Mr Lucas Miehé[3]

[1]Södertörn University, Stockholm, Sweden. [2]University of St.Gallen, St. Gallen, Switzerland. [3]Copenhagen Business School, Copenhagen, Denmark

Abstract

Digitization entails opportunities and challenges for many firms, stimulating business model innovation. While scholars have so far mainly focused on how dominant firms in ecosystems can innovate their business model in response to digitization, we take a different approach and examine how digital service providers can inject themselves into an ecosystem and connect themselves to the business model of the dominant firm. For an ecosystem to be sustainable, the business models of the involved firms need to interact and be aligned. Although the literature on the digitization of business models has grown enormously, the implications of digitization for such interaction and alignment across firms and business models remain under-researched (as pointed out by Kohtamäki et al., 2019; Paiola & Gebauer, 2020; Kapoor & Agarwal, 2017 and many others). Moreover, existing research has mostly dealt with the business models of the central and dominant firms in ecosystems (e.g. Iansiti & Levien, 2004; Williamson & de Meyer, 2012). However, as ecosystems consist of multiple firms and only one or a few can be dominant and central in each ecosystem, many firms will often assume a complementary, rather than a dominant or central role in ecosystems. Based on an exploratory qualitative study of four cases in mobility, we develop an archetype model of sustainable injection strategies. Our findings illuminate complementor strategies in ecosystems and show that the dominant firms in ecosystems do not necessarily have to make cumbersome changes to their business model to accommodate digitization. Rather, they can also cooperate with digital service providers to do so. Our findings add important contributions to the business model innovation with a focus on sustainability and ecosystem literature.

Does Collaborative LCA Improve Engineering Competencies for Sustainability? A comparative analysis

PhD student Lou Grimal[1], PhD Nadège Troussier[1], PhD Inès di Loreto[2]

[1]INSYTE/CREIDD, Troyes, France. [2]LIST3N/Tech-CICO, Troyes, France

Abstract

Engineering activities have been actively participating in the over-coming of planetary boundaries by developing technological artifacts and infrastructures without systematically considering environmental and social issues. Engineering activities are supported by specific IT tools for design and production. In this article, we are interested in those tools and the impact they can have on engineering activities for sustainability, more precisely on engineers themselves.

For a couple of years, students we train are rejecting engineering tools that are dedicated to sustainability, such as life cycle assessment or ecodesign. There are several reasons for this attitude, the main being that those methods and tools seem to act at the product level and not at a systemic level, with no chance to bring macro change. Thus, they are questioning the relevance of learning to master those tools. The authors want to develop knowledge on the impact of those engineering tools on engineers regarding the knowledge, skills, and competencies for engineering for sustainability they can develop. Also, we are wondering if a change in the way we use those tools can help improve engineering competencies for sustainability.

The aim of this work is to better understand how engineering tools for sustainability impact engineers themselves. We have done the hypothesis that more collaborative tools can improve engineering for sustainability competencies. This collaborative aspect is lacking in most engineering tools for sustainability, for instance in life cycle assessment (LCA) tools. Thus, we conducted an analysis to know if adding collaborative aspects in the learning and use of LCA tools has an impact on the development of engineering competencies for sustainability. A comparative analysis has been deployed between a “classic” life cycle assessment and a more collaborative way of practicing LCA. For this comparative analysis, we are observing the evolution of competencies of engineering for sustainability - which are well defined in the scientific literature - and the evolution of students’ understanding of LCA’s relevance for a sustainable transition.

With this study, the contribution is twofold. First, we yearn to better understand the impact LCA tools have on engineers (the evolution of their competencies, students’ understanding of LCA). Second, we are exploring a more collaborative way to use LCA tools and the impact this new feature has on students' competencies - specifically engineering competencies for sustainability. Through this study, we aim to better understand the relationship between engineering for sustainability and the associated engineering IT tools.

Hacking the Campus: Art and creative engagement to design a sustainable environment

PhD Sofia Lundmark, PhD Romina Rodela

Department of Natural Sciences, Environmental Studies and Technology at Södertörn University, Huddinge, Sweden

Abstract

Cities are becoming increasingly complex as a multitude of interests, needs, values and ways of living converge. For this reason, it is important to understand this diversity and explore how it could be captured by planning and governance processes. This is commonly done in participatory spatial planning processes where well-educated, adult, and economically stable citizens would commonly provide input to the process. Younger demographic groups as children and youth are rarely involved. In 2022 Sweden, however, passed an act that states that children and youth shall be part of spatial planning when they are to be affected by given interventions.

There are many diverse good examples of youth participation that offer valuable insights and grounding to this new turn. Yet, youth is not an easy catch. Youth is a very diverse group, and more often than not, they are critical of the status quo, and thrive most when challenged on tasks that they find interesting. Engaging youth in classical workshop sessions with experts discussing maps or models might not work at all. Here some have suggested that art, crafting, and novel technology could help to develop meaningful participatory processes.

In the study presented here, we report on an attempt to explore a novel method. We introduce an activity where 52 students at a media and design bachelor program at a Swedish university explored the use of art and design methods to 'hack' their campus in a post-Covid-19 scenario. The students were asked to work with the design materials – paper and cardboard – to give shape to alternative ideas about how to hack the campus environment. They were asked to develop a "sustainable artefact" representing a solution to the challenge of returning after the pandemic. They were asked to critically look at the current infrastructure and think about what they would like to change to make it a more sustainable place.

The data set for this study consists of 52 assignments including tangible material representations of the work in the form of images of i) the resulting designed artifact (details, work-in-progress, final prototype), ii) of montage images of the designed artifact contextualized and placed into the campus environment, as well as iii) written reflections about the task at hand. The assignments were analyzed using a thematic content analysis and analysis of the sustainable artifacts.

The designed artifacts were created from a range of different ideas and observations. Some were made with the purpose to reduce stress, others to promote mental and physical health, or to boots social gatherings and togetherness. The typology of these spans from artifacts that are inspired by furniture that promotes meetings and social interaction, collective gardening areas, bird nests, litter containers, green houses, training equipment, tools to provide feedback, interactive screens and power stations both for bikes and phones.

This abstract is submitted to SDG+Target: 5b, and relates to the conference theme by providing insights on how art and design can be used to encourage sustainable development of young adults in their own social and urban environment.

Abstract

This research paper presents the work conducted in a French National Research Agency supported project to overcome the issues faced by engineering lecturers willing to integrate socio-ecological aspects of their engineering teaching material. The paper investigates the adapted support, content, and context to integrate sustainability into engineering courses aligned with sustainable future requirements for industries. The literature review identified two main barriers to the dissemination of knowledge on sustainability to higher education lecturer. Firstly, there is a plethora of course materials. However, their format and content are not adapted to properly fit the existing technological courses covered by teachers. Secondly, available courses on sustainability are scattered in several platforms. Concerned with a lack of time, and with very limited guidance support, higher education lecturers are therefore struggling to choose the training material in sustainability that would fit their discipline. The sequence to start with and the level of socio-ecological issues to address are unclearly prescribed. Thirdly, the existing materials rarely allow teachers to share their own skills, and compose their course efficiently. To face them, a collaborative proposition has been formulated by the twelve academic researchers and collaborators involved in this project. The proposition confers three objectives: to facilitate the diffusion of sustainability issues in engineering courses for higher education, to develop and maintain a sharing platform, and to secure a contribution and co-learning network of contributors. The paper presents the first experimentations conducted with teachers and students, covering the basic-level one-sustainability skills for engineers of system thinking, prospective vision, ethic, change, and action. The skills-based framework contains has been developed on a creative common software available on a sharing platform hosted in France by the S.mart community in engineering design. Results show that behind the French engineering community involved in sustainability issues, the sharing principles are strong values to develop and maintain sustainability trainings over the year.

Life Cycle Assessment of a Newly Lightweight Automotive Component Design: Linkage of design for sustainability and the sustainable development goals

Ms. Margarida Gonçalves[1], Mr. Marco Estrela[1], Mr. Zach Georgeou[2], Mr. Kai Köhler[2], Ms. Carlota Arenillas[3], Mr. Michele Tedesco[4]

[1]R&Di unit of Low Carbon & Resource Efficiency, Instituto de Soldadura e Qualidade, Porto Salvo, Portugal. [2]Salzgitter Mannesmann Forschung GmbH, Duisburg, Germany. [3]Gestamp, Bizkaia, Spain. [4]Centro Ricerche Fiat S.C.p.A., Turin, Italy

Abstract

Lightweight materials have the potential to reduce vehicle fuel consumption and greenhouse gas emissions, thus in line with the Sustainable Development Goals (SDG) 13 "Take urgent action to combat climate change and its impacts". Novel 3rd generation advanced high strength steels, based on medium manganese, were developed and integrated into a newly designed component of the Jeep Renegade vehicle. The goal is to compare the environmental performance of the novel ecodesign component with the current Jeep Renegade component based on advanced high-strength steel alloy. To support the Design for Sustainability (DfS) a Life Cycle Assessment (LCA) methodology is conducted following two approaches, namely a cradle-to-gate, to quantify the potential environmental impacts of the production of the component, and a cradle-to-wheel, to evaluate the potential environmental benefits of the new steel alloys at the vehicle use stage. The LCA results show that, depending on the life cycle stages included in the assessment, the DfS results changed for some environmental impact categories, i.e., if the approach was a cradle-to-gate or cradle-to-wheel. The component production with the current steel alloy is the best environmental solution, with an exception for the freshwater eutrophication impact category. However, when coupling all the life cycle stages together, namely material production, manufacturing, and vehicle use stage, the best environmental solution switches to the novel advanced high strength steels based on 3rd generation medium manganese, with an exception for the mineral resource scarcity impact category. Since the use stage is more significant to total impacts than the other life cycle stages, the novel steel alloys production impacts are mitigated. It can be concluded that merely based on a climate change mitigation strategy (e.g., SDG 13; SDG9+Target: 9.4), the results corroborate the application of lightweight materials as a way to reduce carbon emissions. However, when considering the sustainability concept in a broader and more inclusive scope (e.g., SDG 15; SDG11+Target: 11.4,+Target 12.2 and 12.4) conclusions regarding the best environmental solution are involved in some ambiguity since environmental impacts trade-offs are identified when other impact categories are considered beyond greenhouse gas emissions and energy consumption. For the novel steel alloys production, the pickled hot-rolled flat steel production is identified as an environmental hot spot. To improve their environmental performance measures should be implemented to mitigate the mineral resource scarcity impact result.

Supporting Product Planning for a Circular Economy: Evaluation of a case study within the white goods industry

Anna Díaz-Tena[1], Tatiana Reyes[2], Prof. Rupert J. Baumgartner[1]

[1]University of Graz, Graz, Austria. [2]University of Technology of Troyes, Troyes, France

Abstract

The circular economy paradigm is increasingly regarded as a means to achieve sustainable development goals in private sector organisations. This is done through the implementation of value-retention strategies during the design of products, which allow to increase resource-efficiency during production and reduce material throughput during consumption by readjusting consumer behaviour and products lifecycle management. Often, these design modifications are intertwined with competitive strategy elements of the company (e.g., the business model), and thus, designing for a circular economy entails strategic decision-making. Current product development processes often integrate sustainability-oriented requirements once strategic aspects are already discussed upon, and thus, the design space does not allow for implementing transformational circular economy strategies. This research set out to evaluate the performance of computer-based support aiming to improve the effectiveness of value-retention strategy implementation during product development. The computer-aided tool is based on general morphological analysis and describes 6 process factors necessary to integrate high-value retention strategies into the design of products and compiles a range of conditions under which each factor can be implemented, providing product planners the building blocks of their circular economy-oriented product development roadmap. Thus, the tool has been applied and evaluated during strategic product planning in a case study on the white goods industry. The evaluation was based on an experimental design that compared the product planning outcomes (product proposal and implementation roadmap) of development teams where support was either present or absent and measured the impacts of the tool on 15 process effectiveness indicators. The findings of this study shed light on the intra-organisational resources that need to be mobilized for integrating high-value retention strategies during the development of products, thus contributing to expanding the knowledge on circular economy implementation in private sector organisations.

Sustainable Fashion and Textile: Contemporary Scenario

Mr. Siddharth Siddharth, Ms. Pooja Kapoor, Ms. Jyoti Pal, Mr. Chetan Chiller, Ms. Kanika Jolly, Ms. Deepshikha Deepshikha

National Institute of Fashion Technology, Delhi, India

Abstract

Textile and apparel industry contributes significantly towards creating employment and revenue generation, globally. China occupies 50% of the apparel manufacturing sector followed by India, Mexico, Philippines, Indonesia, Bangladesh and Srilanka. The industry is also one of the major sources of land, water and air pollution with over 20,000 chemicals being used are carcinogenic in nature. The paper reviews types of sustainable practices in fashion and apparel industry being followed globally; case studies of popular brands that follow sustainable practices for textile and apparel production in India and around the world; certifications that industries have acquired for sustainable production; and a questionnaire based study with entrepreneurs and consumers about sustainable fashion. Qualitative analysis of the response received from entrepreneurs suggest that they are eager to work on a line of products created purely out of sustainable methods as part of their existing portfolios. They are also optimistic about incorporating sustainable practices in their day to day operations to reduce harmful impact on the environment and acquiring certifications that may benefit their business. The study conducted with young consumers between the age group of 20-40 years reveals that they readily purchase from environmentally conscious labels and intend to increase their share of sustainable fashion in their existing wardrobe for a better impact. The paper concludes with trends for sustainable fashion, textiles and accessories domain for the near future.

Traditional Indian Textile Crafts and Paintings: A sustainable heritage

Mr. Siddharth Siddharth, Ms. Pooja Kapoor, Ms. Jyoti Pal, Mr. Chetan Chiller, Ms. Kanika Jolly, Ms. Deepshikha Deepshikha

National Institute of Fashion Technology, Delhi, India

Abstract

Textile traditions and paintings of India have a rich lineage that represents cultural indigeneity. Textile crafts of India may be broadly classified as woven, printed, painted and embroidered. Many of these crafts employ natural dyeing, painting and printing for preparation of handcrafted textiles. Similarly traditional paintings of India are rich in material wealth, stories and visual creativity. The paper reviews few folk paintings of India, such as Madhubani, Warli, Pithora, Patachitra, Miniatures, Phad, Pahari, Ragamala, Tanjore and craft practices such as Pichwai, Batik, Block Printing Tie-dye, Kalamkari and their usage of natural dyes. Further the authors approached educators, entrepreneurs, students and consumers for their views on sustainable dyeing, printing and painting methods and usage. Qualitative analysis of study conducted reveals that while educators are keen on inculcating sustainable practices in teaching curriculum and their students, entrepreneurs believe in bringing the theoretical knowledge to fruition via local and global retail. Study conducted with young consumers on buying preferences for sustainable products reveals that although natural and sustainable production may render the product expensive, their purchase is high on value and aesthetics and hence constitutes a desirable place in their wardrobe and home interiors. The paper concludes that the future of sustainably produced textile crafts and paintings is quite popular in demand and will continue to remain an essential part consumers' buying preferences. Authors also report few initiatives that may be undertaken that could prove beneficial for the traditional practices, such as online retail, online trade shows specifically for sustainable products, training programs for students and entrepreneurs to incorporate sustainable practices into their learning and product lines, bridging the gap between artists, craft persons, students and enthusiasts by connecting them via virtual or physical workshops.

What a Waste – A norm-critical study on how waste is understood and managed through integrating perspectives

Senior Lecturer Anna-Sara Fagerholm[1], Senior Lecturer Karina Göransson[1], Senior Lecturer Henrik Haller[2], Associate Professor Per-Olof Hedvall[3]

[1]Mid Sweden University, Sundsvall, Sweden. [2]Mid Sweden University, Östersund, Sweden. [3]Mid Sweden University, Lund, Sweden

Abstract

In previous research waste is described as a design flaw, as the processes that generate waste are a result of poor design (Anastas & Zimmerman, 2006; Ordónez, 2017). Ekberg (2009) points out that waste is what is left behind when imagination fails and this also reflects a reconsidering of waste as resources if given another context.

In a globalized world with international trade, there is a greater range of products on the market and the amount of waste is constantly increasing (Avfall Sverige, 2021). A challenge is therefore to reduce the amount of waste. De Laney (2018) points out that there is a huge opportunity to reduce landfill waste and improve consumer habits through design. In this process, we must learn to include new and more inclusive ways of thinking and acting that support long-term social sustainability through design (Wikberg Nilsson & Jahnke, 2018).

More than forty years ago, Dilnot (1982) emphasized that through design, we humans give shape, direction and meaning to our individual and collective existence in the world. Today, there are different design solutions for household waste and recycling and Vollaard and van Soest (2020) argue that reducing unsorted waste normally requires little in the way of capital investment beyond buying a set of in-home recycling bins. Although, many times consumers aren´t aware of the impact of their disposal decisions and many facilities for local waste disposal and recycling have processes that are unique to them that could cause confusion (De Laney, 2018). In accordance, we must find a way to get consumers to care and to motivate a change in habits.

The research question of this study is how waste is understood and managed and this is explored through a case study with a local housing company and waste management company, interested in improving waste sorting. In order to answer the research question, interviews are conducted with people living in the specific buildings belonging to the housing company, respondents from the local housing company and the waste management company and results are presented on perceptions of waste and what the barriers are to improve waste sorting. This is complemented by a literature review to provide a better understanding of universal design and waste.

This paper presents a norm-critical aspect on universal design and waste in a collaborative research project with the objective of creating more inclusive solutions for waste systems. The overall ambition of this study is to build on knowledge of the role of design as an activity of shaping the human surroundings and as an expression of the culture to which it belongs (Skjerven & Reitan, 2018).

The study is related to global goal number 2.5: by 2030, substantially reduce waste generation through prevention, reduction, recycling and reuse.

Sustainable Redesign Process of Foldable Plastic Crate Suitable to Grape Transport

A case study of design optimization end material reduction

Lucia Pietroni[1], Jacopo Mascitti[2], Daniele Galloppo[3]

[1]*University of Camerino, lucia.pietroni@unicam.it*
[2]*University of Camerino, jacopo.mascitti@unicam.it*
[3]*University of Camerino, daniele.galloppo@unicam.it*

Abstract

The transport and logistics system of many fruit and vegetable products, is strongly linked to the production of crates, which mainly use virgin plastics or materials of cellulosic origin, such as wood and corrugated cardboard. Despite the availability on the market of reusable containers, in many countries, such as in Chile and the rest of South America, disposable types continue to be used. To aggravate the environmental burden, there is also the poor management of plastic waste in these territories. In fact, in the new report - drawn up by The World Bank Group - South America prefers landfills (68.5%), but the abandonment of materials on the street is also not uncommon (26.8%). However, signs of change are also taking place in these countries: legislation that restricts the use and distribution of single-use plastics is evolving in Latin America, but the path is still long and complicated. According to one of the latest studies conducted by the Ellen MacArthur Foundation, "current efforts to eliminate plastic remain focused on replacing with other plastic or paper" but also redesigning single- use products and reducing their weight - often by reducing thickness. - represents a valid alternative for manufacturing companies, which do not intend to replace the starting material. The proposed paper intends to describe the process of research and environmental redesign of a disposable plastic tray, foldable and Collapsible, intended for the transport of grapes. The project, developed for the Chilean company "Wenco S.A." from the Spin-off of the University of Camerino EcodesignLab in collaboration with the Italian company “SCS Stampi”, had as a priority objective the reduction of the material used to produce packaging. The product is characterized by innovative technical-formal solutions capable of increasing resilience, drastically reducing the use of polypropylene, and improving its ergonomics for the stacking and transport of the individual boxes. In the first phase of the project, preliminary and benchmarking research was started, aimed at analyzing the technical characteristics of the boxes used for transporting grapes. Through the photographic survey of the product supplied by the company, its weighing and FEM structural analyzes, optimization strategies were identified to reduce the amount of polypropylene used. At the end of the analysis phase, a new proposal for a collapsible box was generated, developed according to the design criteria of the DfS and optimized to ensure optimal

conservation of the grapes during all stages of transport. The redesign process has led to a reduction of polypropylene by 17%, up to 25% in the advanced version of the box. Considering the annual production of approximately 4 million pieces, the results obtained represent an important contribution in terms of reduction of resources and environmental impacts attributable to the production of virgin material. In conclusion, the paper presents a case study in line with the SDG 12 objective, which made it possible to obtain both a significant reduction in consumption and an increase in company know- how, in terms of the manufacturer's DfS.

Keywords: foldable plastic crate, sustainable design, design for reduction, structural design

1. Introduction

The current scenario of the transport and logistics system of most fruit and vegetables is strongly linked to the production of crates, which mainly use virgin plastics, materials of cellulosic origin - such as wood and corrugated cardboard - and in some cases bioplastics. The wooden crates, mainly used in the past, represent the traditional tool for the storage and handling of goods; on the other hand, cardboard models are used for light goods, therefore their application is limited. Plastic crates have been available on the market since the 1990s (Conai, 2018) and, thanks to their production and performance versatility, they have acquired a significant presence on the market, becoming the main choice of large-scale distribution for the transport of food goods over long distances. These containers have the main objective of protecting and guaranteeing the integrity of the goods shipped during the transport phase and at the same time simplifying their handling, in the unloading and storage phases.

A 2021 life cycle comparative assessment study aimed at quantifying and comparing the environmental impacts of plastic crates, corrugated cardboard and wood - according to ISO 14040 and ISO 14044 - will demonstrate that the adoption of the plastic crate is environmentally advantageous - compared to other types - only when there is the possibility that it will be reused several times, thus avoiding the high impacts of production (Del Borghi A. et al., 2021). Despite the availability of reusable containers on the market, in many South American countries - such as Chile - disposable types made with virgin material, generally polypropylene or high-density polyethylene, continue to be used. This choice is mainly determined by their low cost and production efficiency, compared to reusable or bioplastic crates, but also by the lack of responsibility of producers for managing the end-of-life of the product. Much of the production, in fact, is shipped abroad, outside the continent, and only a small portion is used for the internal market, for which it still represents a significant environmental problem. Most of the crates are still destined for landfill disposal, and only rarely are they sent to a recycling chain. In addition to causing serious damage to the subsoil - especially during long periods of exposure - the piles of plastic crates in the streets, together with other waste, feed the image of degradation in the territory and for communities in general. The results of the research

conducted by The World Bank Group confirm the environmental emergency of the end-of-life scenario of plastic waste in South America.

The report contains some data, particularly significant for this geographical area: more than two thirds of waste (equal to approximately 68.5%) is disposed of in some type of landfill, half of which in sanitary landfills (with or without controls environmental and social), or burned, and finally 26.8% end up abandoned on the street (World Bank, 2019).

However, signs of change are also taking place in these countries: legislation that limits the use and distribution of single-use plastics is evolving in Latin America; however, the path is still long, complicated, and far from the models developed by European environmental policy.[1] A first step towards this evolution is represented by the Chilean Pact for Plastics (PCP), of April 2019, promoted by the "Fundación Chile" and the "Ministry of the Environment", and whose objective is to rethink the future of plastic in this country, through the involvement of all the actors of the value chain such as companies, public bodies and NGOs. The initiative is part of the "Plastics Pact Global Network", launched in 2018 by the Ellen MacArthur Foundation in the UK.

Therefore, despite the food transport crates market presents a wide range of reusable product types, most of them made of virgin polypropylene, some large-scale distribution companies present in South American countries, such as Chile, still prefer crates single use. Despite the recent technical and commercial developments in post-consumer plastics and the change in regulations to allow the transport of food in containers of recycled material, there are still many restrictions that limit the development of these types of packaging. In fact, the crates made with regenerated material, can only be used with specific foods that are already equipped with their own natural protective casing (such as garlic, chestnuts, bananas, hazelnuts etc.) and consequently, they are not suitable for the transport of others fruit and vegetables, such as grapes, important for the Chilean market. Therefore, the substitution of the material as the best design solution is not always feasible. However, considering the economic aspects and the criticalities of end-of-life management in these territories, it is necessary to undertake a careful life cycle design, mainly aimed at reducing the raw materials used.

According to one of the latest studies conducted by the Ellen MacArthur Foundation: "Current efforts to eliminate plastics remain focused on replacing them with other plastics or paper"; however, also the redesign of disposable products, and the reduction of their weight - often reducing thickness - represents a

[1] The waste production sector is a strategic sector of environmental policy, identified as such, by the European Union, in agreement with all member states, and establishing - in particular for waste deriving from packaging - the principle of the “Extended producer responsibility”, i.e. attributing the responsibility to those who place the packaging on the market (“polluter pays”), whether they are producers or importers of the same.

valid alternative for manufacturing companies, which do not intend to replace the starting material (Ellen MacArthur Foundation, 2021). For example, the beverage industry - water producers in the first place - has taken a leading role in the packaging market, introducing important innovations in reducing the weight of packaging. The latest generations of polyethylene terephthalate (PET) bottles are 50% thinner and lighter than in the past, maintaining in general the same starting performance through new design and structural optimization solutions.

This paper presents the environmental research and redesign process, conducted by EcodesignLab spin- off of the University of Camerino, of a disposable plastic crate, both foldable and collapsible, intended for the transport of grapes. The project, developed in collaboration with SCS Stampi (Italy) for Wenco S.A. (Chile), had as its objective the reduction and rationalization of the material used. Through a Life Cycle Design approach, and the adoption of analysis tools for structural optimization, a new concept of foldable and collapsible crate, with reduced environmental impact, was developed. The product is characterized by innovative technical-formal solutions capable of increasing its resilience, while reducing the use of polypropylene and improving its ergonomic aspects and to facilitate stacking and transport.

2. The phases of the research: activities, methods, and results

The first activity of the development process of the new crates was characterized by the framing of the design brief, which had, as its main objective, the design of a disposable plastic crates for transporting grapes, which was foldable and collapsible, paying particular attention to both the reduction of material used and the improvement of functional and use performance. Through the definition of the brief, it was possible to understand that the redesign of the crates would have entailed - in addition to economic benefits for the manufacturer - also a significant advantage in terms of environmental sustainability, throughout the entire life cycle of the product. Therefore, the methodology adopted to achieve the objectives inherent in the brief was divided into four macro-phases:

1. historical and benchmarking analysis of the reference product;
2. technical-functional analysis of the collapsible crates model, produced by Wenco S.A (Chile) and survey of environmental criticalities;
3. identification of strategies for material reduction - through the support of the FEM Finite Element Method - and optimization of the transport phase;
4. development and optimization of a new model of foldable and collapsible crate for the transport of grapes produced in Chile.

The first macro-phase was characterized by two important research and in-depth activities: the first focused

on the historical evolution of the grape transport crates, and the second on benchmarking analysis of the products of the main competitors. Through the first research, it was possible to learn how the typological evolution of the crates used for the transport of grapes was strongly influenced by the method of use of the transported goods: for wine grapes, in fact, containers in wooden slats were used, carried on the shoulders to the cellar - or in case of long distances, on the back of mules - while, the table grapes - intended for consumption - were harvested in baskets, or cane and wicker containers.

Towards the end of the nineteenth century, the increase in the demand for fruit consumption, the progress of transport technology and finally, the birth of the canning industry, have strongly changed the dynamics of the fruit and vegetable trade worldwide, and have pushed the market of crates to the development of types of products capable of responding to different requests. The evolution of this product is still today a sensitive design issue for many companies, especially for those that transform plastic, and who are interested in innovating and developing new types of crates, in response to new market trends. Although there is already a wide range of products, diversified mainly by transport capacity and type of material, there is a need to implement catalogs through the development of reliable products, suitable for the most recent regulations, and environmentally sustainable, especially in the scenario of their end-of-life. The second activity foreseen in the first phase of the project focused on benchmarking research and on the definition of the state of the art of plastic crates for transporting grapes. The objectives were to identify the main competitors and describe the technical characteristics of the products. To organize the data, product sheets have been developed, in turn divided into three sections: description of the manufacturer's brand and image of the reference product; material and dimensional characteristics (load capacity); structural and ergonomic analysis of the crates.

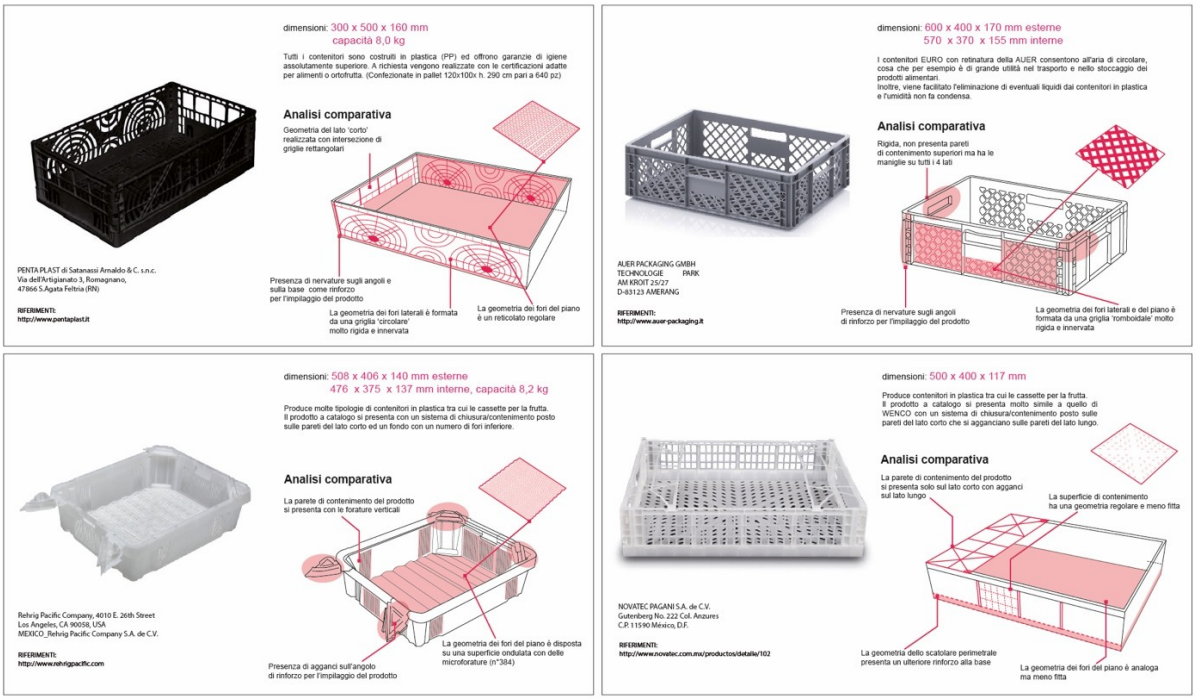

Figure 1. *Examples of product sheets elaborated in benchmarking research activity.*

From the benchmarking study (Figure 1) it was possible to extrapolate a series of final observations and reflections:

- most of the products are made of polypropylene (PP) and high-density polyethylene (HDPE);
- the polymers used for the crates intended for the transport of grapes are mainly virgin, resulting from the main reference regulations (e.g., EC no. 1935/2004);
- injection molding is the only transformation technology used for these types of products and, considering high annual production batches, complex molds are developed with multiple handling for the management of undercuts (this also implies implications for energy consumption and consequent CO2 emissions);
- the transport and handling of the fruit-filled crates by the operators is an underdeveloped aspect and only the non-collapsible types have clearly developed grip points and handles within the containment structure;
- most of the crates use standard mesh, rectangular or rhomboid layouts.

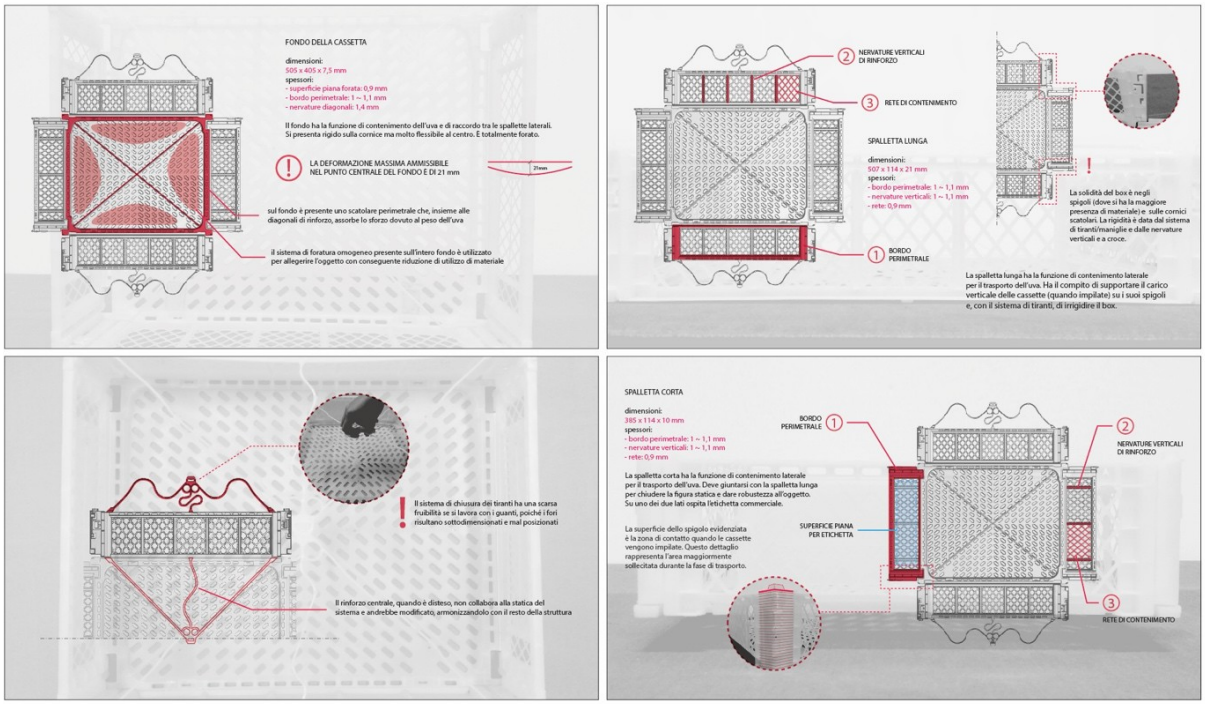

***Figure 2**. Functional and structural analysis of the product Wenco G9-54117A.*

The second macro-phase was intended to describe and analyze the technical-performance and structural characteristics of the plastic, disposable, foldable and collapsible crates for transporting the "WENCO G9-54117A" grapes, highlighting the critical issues. The product has a maximum size of 508x406x117 mm, its transport capacity is 9.2 ~ 9.5 Kg of grapes and has a total weight of 365 g. The crate is single material, made of polypropylene (100% virgin), with injection molding technology, and with an expected annual production of about 4 million pieces. The product has been developed to be stackable vertically (up to a maximum of 17 elements) and stackable, both on the long and on the short sides, to optimize the storage and transport phase. Furthermore, the crate is tested to withstand a compression force of about 440 Kg for 3 hours at a temperature of 20 °C under static load conditions. The containment structure is made up of five elements - two long sidewalls, two short and a bottom - joined together by plastic hinges, to create a single piece, molded in PP. The fund is structurally divided into three parts: a perimeter structural frame (1.1 mm thick); a containment surface (thickness 0.9 mm); two diagonal reinforcement ribs (1.4 mm thick). The containment surface is characterized by a pattern of rectangular and rounded holes and has the function of retaining the grapes and connecting the lateral sidewalls. The maximum deformation admissible in the central point of the bottom is 21 mm, since beyond this value there is a risk of damaging the fruit when the crates are stacked together. The mesh is homogeneous, and the dimensions of the holes are designed to lighten the object and at the same time avoid compromising the integrity of the berries. The two long

sidewalls mainly consist of three functional areas: a structural frame (1.1 mm thick); a containment net (thickness 0.9 mm); four vertical reinforcement ribs. These have the function of lateral containment and help to support most of the vertical load of the crates loaded with grapes when stacked during storage. In fact, they have - on the edges - small connectors to facilitate the centering and stacking of the crates on top of each other. Furthermore, on the short sides, there are both the connection system and the tie rod system, designed to brace and give greater rigidity to the entire crates. This system offers a single gripping point with poor usability - especially if you work with gloves - since the holes are undersized and poorly positioned. Furthermore, it has been observed that the central reinforcement of the tie rod does not cooperate with the statics of the product and is therefore to be considered superfluous and not very functional, with the general statics of the crates. The short sidewall is structurally articulated like the long one and has the function of lateral containment and a joining and closing element for the entire crates system. In addition, on one of the two sides there is an area intended to house the commercial label of the transported product.

In conclusion, from the structural analysis of the crate (Figure 2) it was observed that:

- the solidity and resistance of the crate is mainly generated by the edges and structural frames of the individual elements, in which the greater presence of plastic material was also detected;
- a part of the rigidity, even if minimal, is given by the system of tie rods / handles, and by the vertical and diagonal ribs;
- the edges of the crate represent the critical points, being most stressed during the transport phase;
- the crate mounting system is characterized by a reversible connection system, albeit inconsistent with the end-of-life of the product, which is destroyed and disposed of at the end of its use.

Through the data collected from the structural analysis, it was possible to make a first estimate of the environmental footprint of the product production phase (Table 1). For a batch of four million pieces, 1460 tons of polypropylene are needed. The production of this quantity of polymer requires 262,800 cubic meters of water and approximately 10.6 GWh of energy, which generates approximately 2.6 t of

CO_2 equivalent emissions.[2] Therefore, optimizing only the production phase and reducing - albeit in small percentages - the amount of material through appropriate design strategies, would still imply a significant reduction in the use of environmental resources and impacts associated with the product life cycle.

[2] Considering that to produce 1 ton of plastic it takes 21.4 barrels of oil, 180 cubic meters of water, 7,600 kWh of energy and 1.84t of CO_2 (2020, BIR).

Table 1. *Main impacts and resources for 4 million pieces production.*

	material (ton)	water (mc)	energy (GWh)	CO_2 emission (ton)
4 mln pz.	1,460	262,800	10.6	2.6

3. Macro-strategies for material reduction and transport optimization: experimental tests and FEM analysis

Following the preliminary research and the definition of the brief, with the identification of the design requirements, a first design phase was started for the reduction of plastic material, through the definition of a series of lightening strategies. This preliminary analysis and product architecture improvement work was supported by experimentation and FEM analysis activities, aimed at validating the solutions developed. To achieve the set objectives, a series of structural optimization interventions have been proposed appropriately reasoned on each functional element of the crate.

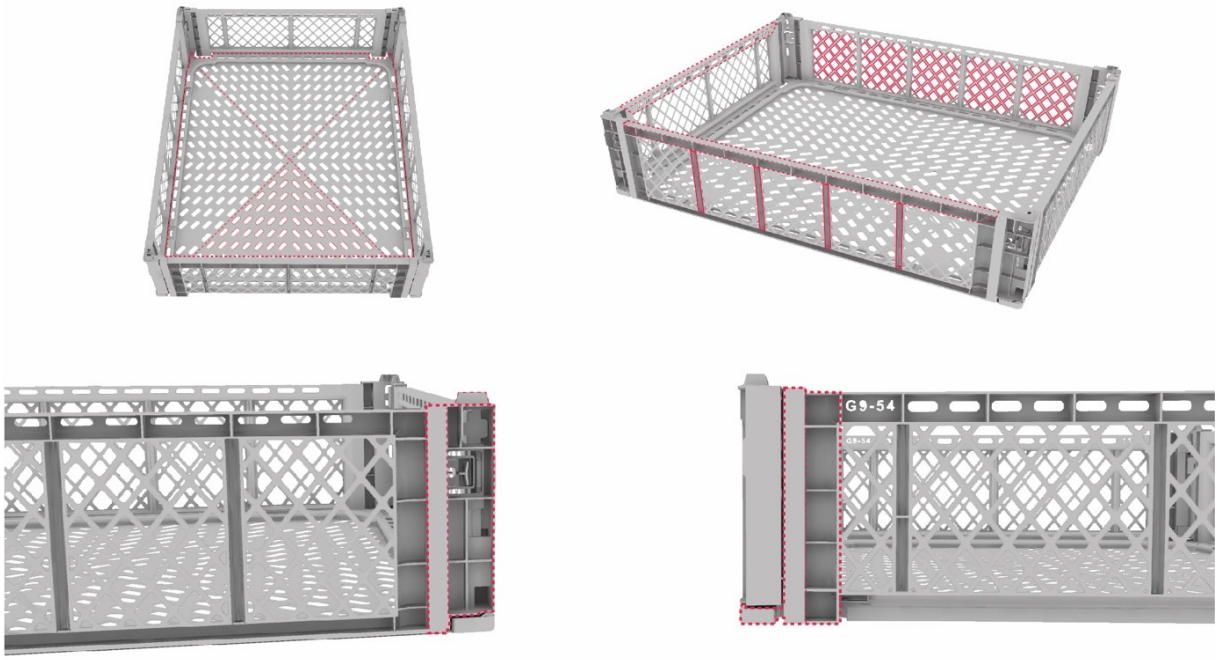

Figure 3*. Overview of the structural optimization interventions.*

Starting from the lateral sidewalls (Figure 3), four macro-strategies have been identified, three focused on the containment parts and one on the reversible interlocking system of the corners:

1) the geometry of the perimeter crate can be optimized by varying the pattern of the ribs and holes: it has

been noted in fact that the pitch of the ribs is always the same, regardless of the effective resistance required - especially for those areas that are not very stressed (for example, in the intermediate sections between the center and the edge of the folding sidewall the bending stresses are less);

2) the rhomboidal mesh containment surface can be redesigned on the basis of the most stressed areas and reduced in thickness in the least critical points;

3) the vertical ribs can be integrated within the containment surface avoiding significant thicknesses. Furthermore, it is reasonable to rethink a single reinforcement solution, positioned in the most stressed point (for example developing a single rib system in the center of long sidewalls);

4) the connection between the sidewalls can be simplified, passing from a reversible 90° joint to an irreversible snap-fit, given the disposable nature of the product.

Through the redesign of the layout and geometry of the interlocking system for the long-sidewall/short-sidewall connection, it would be possible to reduce some thicknesses and the amount of material used with the same performance. For the bottom of the crate, three macro-strategies for lightening and structural optimization have been identified:

1) the geometry of the structural frame - as well as that present in the sidewalls - has a series of uniformly distributed ribs that can be optimized, based on the loads and stresses that the product undergoes throughout its life cycle;

2) the plastic hinges for the overturning of the sidewalls develop along the entire perimeter of the bottom, but a portion of the hinge would be sufficient to obtain the same performance. For example, three short hinges can be developed along the edge, rather than one that is continuous. Furthermore, the position of these generates along the edges a sort of double wall between the sidewalls and the bottom, therefore this doubling and waste of material could be avoided by reconfiguring the position of the hinges;

3) the pattern of the holes in the bottom, can be redesigned and programmed, based on the most stressed areas.

In fact, it was observed in the tests that the perimeter areas are those that are most affected by the stress, compared to the central portion. Once the main macro-strategies for the optimization and reduction of the plastic material were defined, analysis of resistance to static stresses was carried out, first on the starting physical product, and then on the digital model, through a FEM calculation software - (Finite Element Method). The test on the physical model had the purpose of verifying the ability to resist the design load, and to fall within the deformation limits established for the bottom of the product. In the first test, with 9.5 Kg corresponding to the weight of the bunches of grapes, the crate showed no criticality. In a second test - with double load compared to the previous one - the mechanical resistance of the bottom still appeared

sufficient. Instead, the critical deformation of the surface was highlighted, beyond the limit of 21 mm established in the design brief. A second phase of analysis was carried out using the FEM software, on the subcomponents of the crate (tilting sidewalls and bottom) with the aim of verifying the behavior to bending stresses generated by the weight exerted by the grapes. Four scenarios were analyzed for the sidewalls: three in bending and one in compression. The models verified by the FEM are described below:

- a sidewall that presents the structural frame with a series of ribs arranged according to a diagonal layout;

- a sidewall that presents a reduction in the number of vertical ribs, to two large ones arranged in the center of the bank;

- a rhomboidal containment net, with the mesh section rotated by 90° (also valid for the bottom mesh of the crate);

- a sidewall with a snap-fit interlocking system, with reduced use of material, subjected to a compressive stress (to simulate the 17 stacked crates).

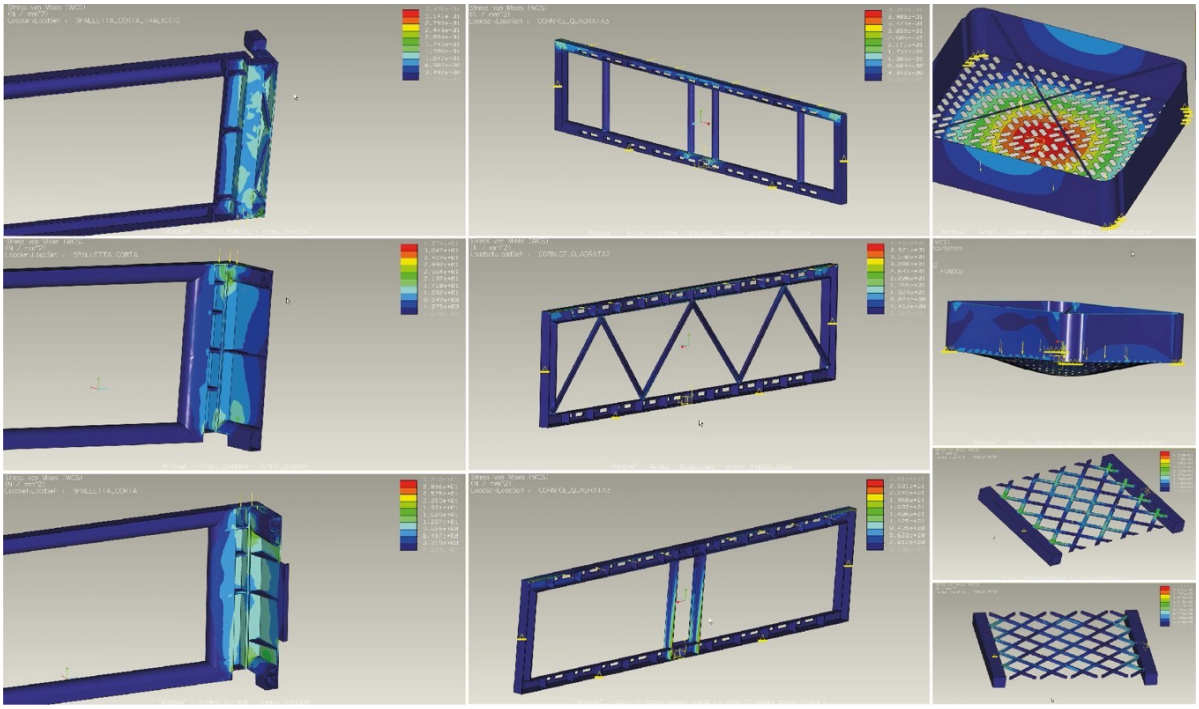

***Figure 4**. Preliminary FEM analysis.*

From the results elaborated by the software (Figure 4) it was possible to deduce that:

- the development of two large central ribs has improved and reduced the deformation phenomenon, generated mainly by the flexural forces which manifest themselves in a marked way in the central point;

- the structural frame of the sidewalls, with the system of ribs arranged according to a diagonal layout, has

proven to be able to increase the general performance of the structure, with less use of plastic material;

- by moving the attachment system from the corner, and studying a new layout of ribs, suitable for resisting the compressive forces, it is possible to use less material, obtaining the same resistance;

- the rhomboidal mesh significantly increases its flexural strength performance if the section is 90° rotated compared to the traditional one.

However, it should be considered that a section of this type risks generating a "blade effect" and damaging the fruit, especially at the bottom of the crate.

4. Design of a collapsible crate for the transport of grapes with reduced use of plastic material

Considering the results obtained from the tests, and therefore verifying the mechanical resistance performance offered by the new analytical models, optimized according to the macro-strategies identified, a design phase was carried out for the elaboration of a new concept of collapsible crate, with reduced consumption of plastic material for transporting grapes.

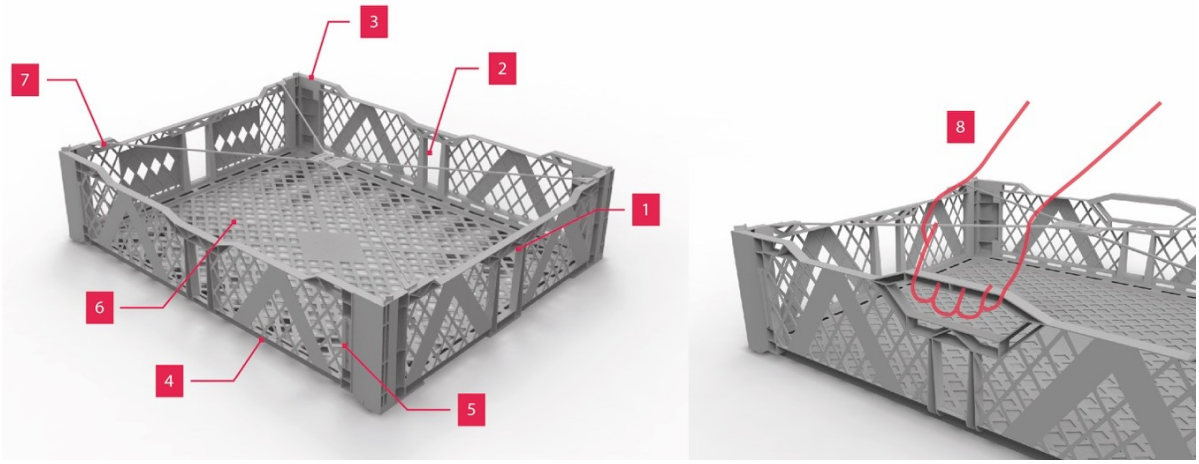

***Figure 5**. Overview of the eight design solutions.*

The product conceived (Figure 5), in addition to guaranteeing the same transport and folding capacity, and perfectly responding to the design requirements defined in the brief, presents an innovative design, characterized by the implementation of eight new design solutions, which distinguish it from the previous model:

1) a perimeter structural frame with a system of ribs arranged in a diagonal layout, inserted in specific portions of the product with higher resistance requirements;

2) a lowering of the long sidewall of 12 mm in the central section, to further reduce the deformation of the product, especially when it is loaded with fruit;

3) a trellis system (Figure 6), positioned in the center of the containment sidewalls, and optimized to withstand the flexing stresses generated by the weight of the grapes during transport and storage;

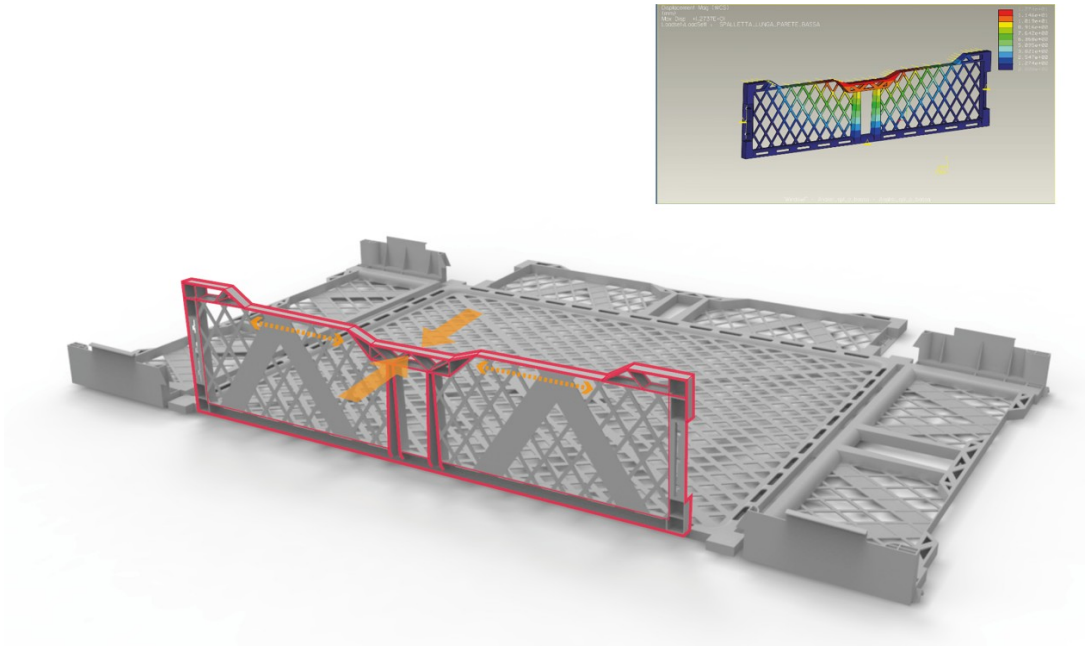

***Figure 6**. The new sidewall trellis system and its structural behaviours.*

4) a system of plastic hinges, reconfigured with respect to the traditional product, which reverse the direction of overturning of the sidewalls - to avoid the doubling of material - and which present, on the short side of the crate, (the structurally less critical one) two lightening slots;

5) a new connection system (Figure 7) with an "L" layout, characterized by a snap-fit joint, with high mechanical resistance and reduced use of material;

6) a new containment net of the bottom, characterized by a rhomboid pattern, and with an optimized cross ribbing, to better resist bending, through the development of a "T" section;

7) an optimized bracing system, without the use of central tie rods, in order to further reduce the amount of plastic material;

8) a carrying handle, integrated into the trellis system of the long sidewall - not included in the brief - but which significantly improved the ergonomics of the product.

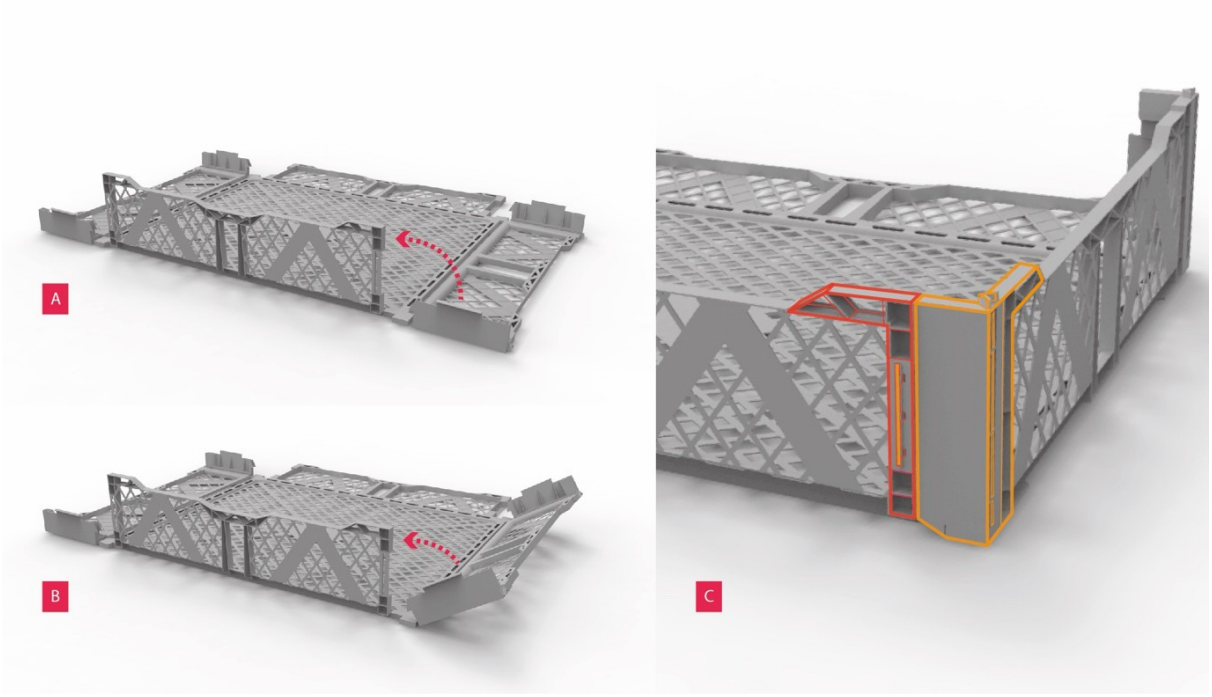

***Figure** 7. The new irreversible connection system "L" shaped.*

In addition to the characters listed above, the new product has maintained some important design aspects, already present in the previous version: four connectors for centering and stacking the product; an area on the short sidewall, intended to house the label for the information of the goods; the connection of all the components, in order to generate the product through a single molding process; geometries that do not involve the generation of undercuts or additional mold movements. The analytical model of the new crate was further verified at the FEM, to confirm the results obtained in the preliminary analyzes, and to evaluate the performance achieved, compared to the old model. A comparative analysis of the deformations between the old and the new layout of the bottom of the crate was carried out first, and then a static evaluation of the new sidewalls was carried out. The design solutions developed have led - each with different contributions - to a significant reduction in the quantity of plastic material. In fact, with the same volume and transport load, the new version of the crate has an estimated theoretical weight of 304 g, which is about 17% less than the old model. Furthermore, the version of the crate with the integrated handle does not generate any material increase; on the contrary - in addition to optimizing the transport and use phase of the users - it generates further structural and static benefits in the stacking phase.

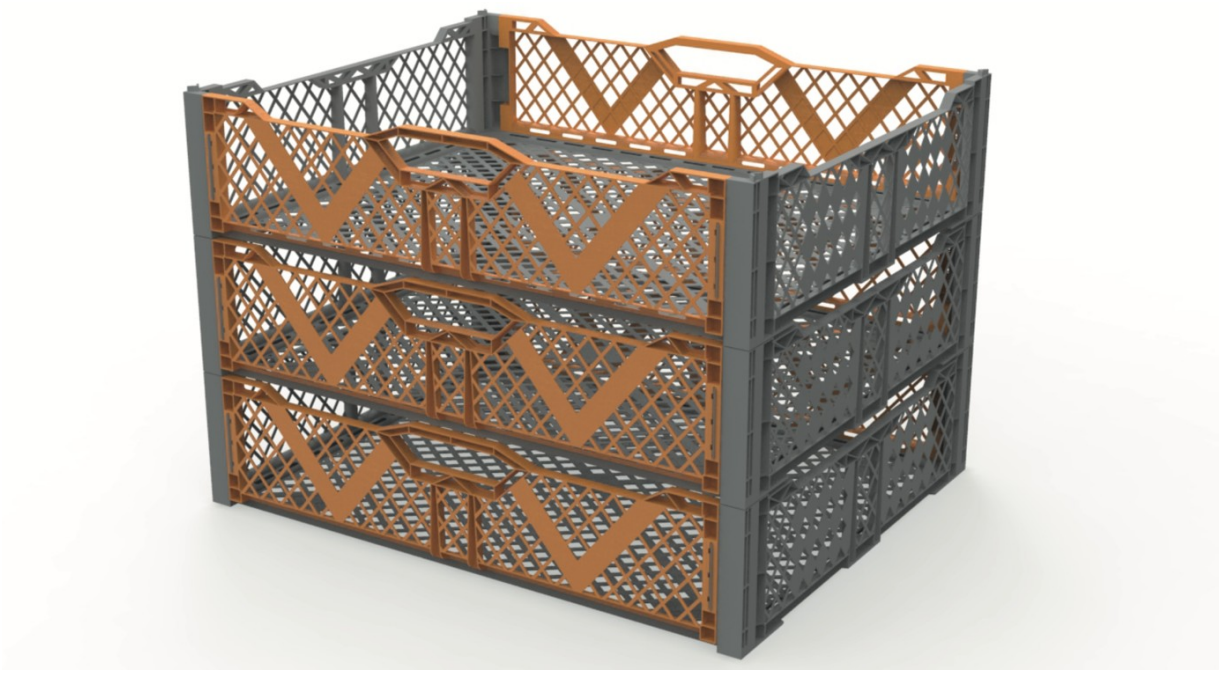

***Figure 8**. Rendering of stacked crates.*

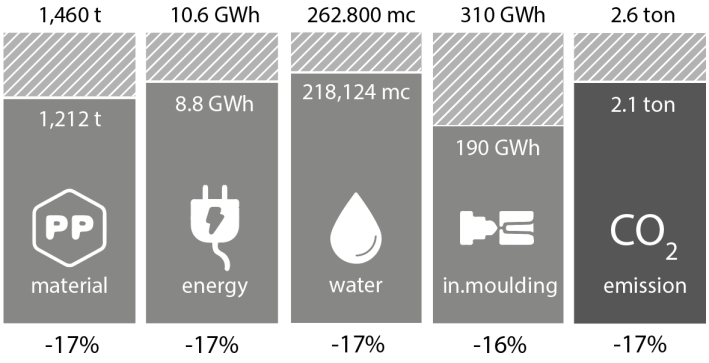
Indeed, as shown in figure 8, the handle in the central part of the sidewall can get stuck under the crate, further reducing the possible deformation of the long sidewall. Through the optimization and reduction strategies of the plastic material, it was also possible to reduce the environmental impacts associated with the production phase of the crate. It has been estimated that the saving of 61 g of polypropylene also generates a considerable reduction in the consumption of raw material, resources and energy associated with the production of plastic material, with estimated values shown in Table 2.

***Table 2.** Estimated reduction of impacts and resources thanks to the new design.*



It should be considered that the reduction of plastic material, obtained with the new design, also implies an

optimization of energy consumption, associated with a lighter product (Vezzoli, 2017). In fact, it is possible to estimate: a reduction associated with the energy of the injection molding press, around 16%, or about 116 GWh less per year (considering the batch of 4 million pieces); a reduction in the energy used to transport the raw material to the gate of the plant; a reduction in transport associated with product distribution and end of life. Finally, for the new concept of collapsible crate, aesthetic and structural variants have been developed, mainly referring to the design of the containment mesh present both on the bottom and on the four sidewalls. The second version of the bottom (Figure 9), involves the development of a pattern of ovoid-shaped holes, characterized by a "T" section to increase mechanical performance but without generating sharp edges, which can affect the state of conservation of the grapes. Unlike the sidewalls, we opted for a mesh solution, which has a reduced thickness section, and which is rotated. Although the latter solution could represent a cutting edge, its location on the sidewalls of the crate does not represent a critical issue for the goods. Finally, it is estimated - based on the values derived from the digital model - that the solutions developed for this second version could reduce the consumption of plastic material by up to 22%. Therefore, a further economic and environmental improvement of about 5% would be obtained, compared to the advantages already estimated for the first version.

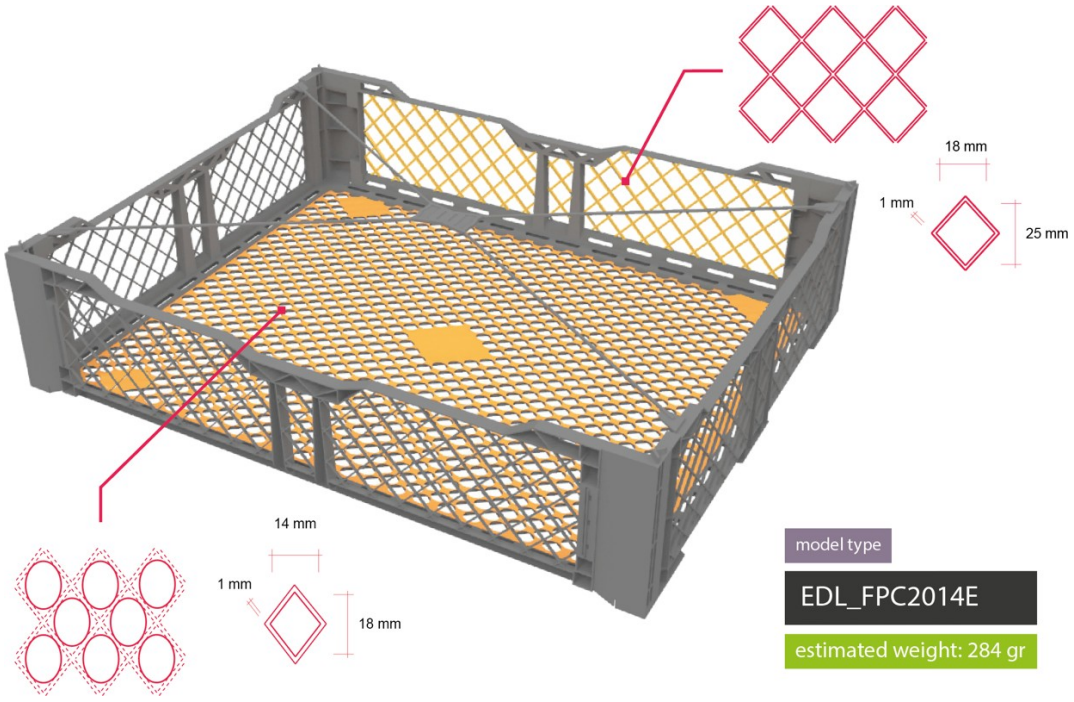


***Figure 9**. Bottom and sidewall mesh solutions of the second version.*

5. Conclusions

The results presented in the paper, showed in Table 2, were achieved through the methodology shown, applying the DfS criteria, to the development of a new concept of collapsible and stackable crate for the transport of grapes. The considerable advantages compared to the starting product "Wenco G9-54 117 A" can be summarized in:

- rationalization of the plastic material, through new structural layouts;
- optimization of the technical-production aspects of the individual functional elements and in particular of the interlocking connection system;
- design of new formal and functional strategies, to make the crate easily transportable in all phases of use.

The macro-strategies of the DfS, mainly aimed at rationalizing the material used, have shown that it is possible to reduce the use of polypropylene, guaranteeing the same starting performance and - in this specific case - even improving some aspects of the usability of the product, making it, therefore, more eco-efficient. [3] In conclusion, the DfS strategies, assisted by the use of the FEM software, mainly adopted as a tool for critical reading of the morphology and static analysis of the product, have allowed the development of a new concept of collapsible crate, which uses between 17% and 22% less plastic material. The material reduction strategies, as described in the paper, have resulted in both economic benefits for the company and a considerable optimization of the environmental impacts of the production, transport and - to a small extent - even the end-of-life phase of the product. The encouraging results open the scenario to further development of this type of product, whose potential for innovation has been demonstrated, through the strategic lever of eco-design. The results obtained are significant and demonstrate the potential for innovation that the DfS offers to designers and companies interested in developing products that are sustainable and competitive.

[3] The term "eco-efficiency" indicates the relationship between the value of a product (intended as satisfaction of the service and performance offered) and the corresponding associated environmental resources.

Application of social cohesion cards tool for mental health in graduate context

Introduction

There is a growing demand for quality mental health services. Many goals set by various countries for mental health have not been resolved at 2020 (Mental health atlas, 2020). There is an urgent need to increase investment in mental health services and it was possible to notice that COVID-19 pandemic has aggravated this situation (United Nations, 2020). In the context of graduate mental health, the scenario is alarming. In Brazil, about 44% masters (M.Sc) and 56% doctorate (Ph.D) degree reported excessive psychological suffering. These sufferings affect different areas of their lives, not only academic, but also social and professional areas (Costa & Nebel, 2018). There are still few studies focused on the mental health of graduate in Brazil (Viana & Souza, 2021). It's a complex problem that creates opportunities and demands efforts from the Design creative process. It can be said that social cohesion can contribute to alleviating symptoms of psychological distress in the graduate context. It's a prerequisite for people to obtain a minimum level of well-being. And, it's the way to build a more sustainable society (SANTOS et al., 2019). In this sense, this study aim to apply a Service Design tool in order to understand how the values of social cohesion can contribute to the mental health in graduate context.

Method

This study it`s a Research phase of the method by Stickdorn, Hormess, Lawrence & Schneider (2020), This is Service Design Doing (TiSDD). The cards tools were created through an unsystematic review of literature. The tool used was the cards with a focus on the values of social cohesion, such as: trust, humility, reciprocity, freedom, fraternity, equality, honesty, loyalty, tolerance, courtesy, optimism, perseverance, respect and solidarity (Dempsey, 2009; Search for Common Ground, 2016; Santos et al., 2019). In total, 14 cards were created.

Figure 1 - Examples of social cohesion cards tools.

Conclusion

Cards helps in the discussion, structuring of thought and generate ideas (Service Design Tools, 2021). The tool was applied during a workshop, in Brazil, entitled Graduate Mental Health. Among the results obtained, it can be noticed that each value is relevant and can contribute to the mental health of graduate context. However, these aspects need to be shared and experienced by the academic community. Cards with a focus on social cohesion helps to understand the relevance of each value, but it still requires improvement. For example, a guide for application the collected data and the participation of members of the same group to better understand the sharing of values. Such aspects can contribute to advance to the Ideation phase of Service Design. The tool proved to be relevant to point out paths to be explored, especially when dealing with a complex problem such as mental health. This abstract contributes to the sustainable development goals (SDG) 3, target 3.4.

Table 1 – Examples of ideas through social cohesion cards tool

Social Cohesion values	Ideas
Trust	Self-esteem tends to increase, there is security in the development of the proposed tasks, expansion of creativity and proactivity.
Reciprocity	From the perspective of the other, I can value myself and understand that there are several types of knowledge in the integral field of my partner.
Fraternity	Provide opportunities for speaking and active listening for the development or improvement of the fraternity.

Implications of Design for Sustainable Behavior Strategies applied to cooking appliances in the Brazilian context

INTRODUCTION

Cooking activity has incorporated new values and practices, in addition to meeting physiological needs. Thus, concomitant with the search for healthier eating, there is an interest in more intimate gastronomic experiences, which invite spending more time with friends and family and as a therapeutic activity. In the present study, the integration of Design for Sustainable Behavior strategies is analyzed through the model proposed by Bhamra et al. (2011), which includes strategies oriented to the user's greater or lesser control in decision making during product usage.

METHOD

The survey research was adopted to identify good practices and gaps in cooking major appliances regarding Design for sustainable Behavior Strategies (Bhamra et al., 2011). The benchmarking process evaluates its repercussions in a sample of 151 products, stoves, and cooktops, manufactured in Brazil by the eight industries members of the Brazilian Association of Electrical and Electronic Manufacturers (ELETROS).

RESULTS AND DISCUSSION

COMPANY (ELETROS)	COOKING APPLIANCES w/ DfSB	DfSB STRATEGIES (Bhamra et al., 2011)	USER CONTROL (Lilley, 2007)	BEHAVIORAL CHANGE INTERVENTION	INDIVIDUAL ACTIONS	GENERAL ACTIONS
Atlas	-	-	-	-	-	Recommendations to save energy and to ensure security by instruction manual
Electrolux	6	Clever Design	Low	Ensure	-	Recommendations to save energy and to ensure security by instruction manual
LG	-	-	-	-	-	-
Midea	5	Clever Design	Low	Ensure	6	Recommendations to save energy and to ensure security by instruction manual
Mueller	3	Clever Design	Low	Ensure	3	Recommendations to save energy and to ensure security by instruction manual
Panasonic	1	Eco-information	High	Guide	1	Recommendations to save energy and to ensure security by instruction manual
Tramontina	1	Eco-choice	High	Guide	1	Recommendations to save energy and to ensure security by instruction manual
Whirpool	2	-	-	-	1	Recommendations to save energy and to ensure security by instruction manual

CONCLUSION

Despite the several technological resources applied on the cooking appliance interfaces and the continuous industrial concern in using materials, processes, and resources that generate less environmental impact, few efforts are addressed to influence more sustainable behaviors in the products' use phase, representing a theme with great potential to guide innovation agendas in the sector.

A Critical Analysis and Comparison of Circular Economy Policies in three European Cities

Martin Calisto Friant[1], Katie Reid[1], Peppi Boesler[1], Walter J.V. Vermeulen[1], Roberta Salomone[2]

[1]Copernicus Institute of Sustainable Development, Faculty of Geosciences, Utrecht University, Utrecht, Netherlands. [2]Department of Economics, University of Messina, Messina, Italy

Abstract

The Circular Economy (CE) concept has recently become a popular discourse in the public, private, academic, and social sectors alike. However, the concept remains contested, often unclear and ill-defined, thus its practical implementation remains a large societal challenge. Cities and urban areas play a central role in the CE as they are directly in charge of key sustainability policies, such as waste management, water provision, transportation, housing, industrial development and energy and infrastructure provision. Urban circular economy policies thus have a key impact on the metabolic stocks and flows of resources, waste, capital, labour, knowledge, energy, and materials that societies process (the so-called urban metabolism). Considering that urban areas currently consume 60–80% of the world's natural resources, produce 50% of global waste and 75% of greenhouse gas emissions, CE policies at the city level are crucial to address the manifold social-ecological challenges of the 21st century. In this context, European cities have developed a wide diversity of new CE policies and projects, with many different, and often contrasting, CE discourses and perspectives. Yet these initiatives remain poorly researched, compared, and critically analyzed. This research thus aims to address this research gap by analyzing and comparing the CE policies and discourses in different European cities to draw key lessons and recommendations. It does so by first conducting a critical literature review of academic research on CE policies at the city level in order to develop a new conceptual framework to analyze CE discourses and policies. This framework is then used to critically analyze and compare the CE policies of 3 European cities at the forefront of the CE transition: Glasgow, Amsterdam, and Copenhagen. Results show a diversity of approaches to circularity, with each city having a different scope and vision, especially regarding social justice and equity considerations. Moreover, approaches to CE based on technology and economic growth appear dominant in the chosen case studies. These findings thereby suggest that more diversity and plurality is needed in CE policies, especially including post-growth and post-development approaches to circularity. This research concludes by providing key policy recommendations to improve CE implementation at the city scale, which are valuable for practitioners and academics alike and can contribute to SDGs 6 (water and sanitation), 9 (infrastructure), 11 (cities), 12 (production and consumption), 13 (climate change), and 15 (life on land).

Adapting Circular Packaging Design from an Absorptive Capacities Perspective - theoretical perspectives and practical insights

M.Sc. Lukas Stumpf, PhD Josef-Peter Schöggl, Prof. Rupert J. Baumgartner

Graz University, Graz, Austria

Abstract

An increasing number of circular product design guidelines (CDGs) has become available in the packaging sector in the last years., while their uptake in practice remains low. Considering this emerging omnipresence of external knowledge represented in these CDGs, barriers to their implementation into corporate decision-making may hinder their more widespread application. While several studies define barriers for design for sustainability/circularity (DfS) in different areas, a detailed account of these barriers for the packaging sector is missing. Moreover, most of such barrier-related studies don't build on organizational theories. Therefore, potential causalities and interdependencies between the different barriers sometimes remain uncertain. This study aims to identify barriers to the uptake of CDGs in the packaging sector from an absorptive capacity (ACAP) perspective. ACAP theory is considered well suited for this study as it focuses particularly on the recognition, assimilation, and application of external knowledge, including antecedents and moderators.

The determination of ACAP-based barriers builds on a three-step approach: (1) A systematic literature review of DfS barriers and circular packaging design literature, including grey literature, was performed to understand the sector's circular economy engagement. Next, (2) qualitative semi-structured interviews with senior executives of companies responsible for packaging design were conducted. (3) Finally, the barriers were synthesized in the ACAP model, and potential interdependencies, causalities, and ways for overcoming the barriers were described qualitatively.

Preliminary findings can be logically separated into two steps: (i) deciding which external knowledge to absorb and (ii) its operationalization.

Step (i) largely depends on antecedents and moderators, such as previous collaborations or external involvement. Furthermore, if CDGs are only considered if all other KPIs are equal (shelf life, etc.), while the industry continues to develop composites with superior functionality, CDGs might not be prioritized. Such decisions may essentially be dependent on managerial experience, organizational strategy, organizational priorities, or perceived usefulness (i.e., recyclability vs actually recycled material). Following a passive approach and passing responsibility on in the supply chain might lead to a chicken-egg problem, reinforced by supply chain power structures.

For step (ii), operationalization, internal capabilities, and organizational ties and collaborative relationships are decisive for successful knowledge integration. Consequently, if a company does not possess the capabilities to integrate CDGs (e.g., due to a lack of communication or priority, or because its integration requires management approaches unknown to the company, such as close cross-departmental or supply-chain wide collaboration to test prototypes), it will fail to acquire, assimilate, transform, and exploit CDGs.

The study concludes with recommendations to overcome the identified barriers for both companies in the plastic packaging supply chain (to enable them to recognize and integrate CDGs) and CDG developers (to ease managerial uptake and valuation).

This research contributes explicitly to SDGs 14.1 (reduce marine pollution of all kinds), 17.16 (enhance multi-stakeholder partnerships for sustainable development), 12.2 (sustainable management of natural resources), 12.4 (sound management of chemicals and waste), 12.5 (reduce waste generation). It relates to

2022's ISDRS topic by addressing corporate innovation and culture as a lever for sustainable resources management.

Assessment Model of Circular Economy Implementation: A proposal for Latin American SMEs

Dr. Andrés Mejía-Villa[1], Dr. Luz Elba Torres-Guevara[1], M.Sc. Rafael Mora-Contreras[1], Dr. Vanessa Prieto-Sandoval[2]

[1]Universidad de La Sabana, International School of Economic and Administrative Sciences, Chía, Colombia. [2]Pontificia Universidad Javeriana, School of Economics and Business, Bogotá, Colombia

Abstract

Currently, it is widely accepted that a circular economy (CE) is key to facing many economic, environmental, and social issues worldwide while contributing to the achievement of the SDGs. Due to its relevance, some Latin American governments are promoting and supporting the implementation of CE. Colombia is one of the regional leaders that has made the most progress in implementing CE initiatives, thanks to the National CE Strategy that the government launched in 2018. The record of the CE implementation progress oversees the National Administrative Department of Statistics, which has produced four reports at the country level. However, a report that evidences the CE implementation at an organisational level and allows companies to make decisions has yet to be developed.

For this reason, this research aims to propose a model for the CE implementation and a virtual tool to capture information, produce diagnostic reports to help the SMEs to become circular enterprises and support sustainable decisions based on special key performance indicators (KPIs). To achieve this objective, we worked with ten Colombian companies representing different economic sectors and levels of implementation of the CE. All this with the financial support of the Chartered Institute of Management Accountants (CIMA). A mixed methodology (qualitative and quantitative) based on visits to the companies, interviews and accounting data collection were used to construct the KPIs. The results show that this model represents an opportunity for SMEs to identify their level of maturity and, therefore, to define future actions that allow them to advance in CE implementation.

Assessment of Circular Economy Scenarios in the Mineral Water Production Sector

Dr. Erik Roos Lindgreen[1], Prof. Roberta Salomone[1], Prof. Tatiana Reyes[2]

[1]University of Messina, Messina, Italy. [2]UR INSYTE, Troyes, France

Abstract

The mineral water sector is responding to changes in legislation and consumer demand by evaluating the introduction of different circular economy (CE) strategies. In order to assess the (environmental) sustainability impacts of such strategies, the newly designed CE assessment framework Strategic Circular Economy Impact Assessment (SCEIA) is tested in a pilot case setting with an Italian mineral water company. Applying the life cycle assessment (LCA) method for the environmental assessment results in the baseline sustainability impacts of the company. Subsequently, the selected methods are used in a subsequent sustainability assessment of three potential CE strategies: (i) the increased use of recycled PET (rPET) in its packaging, (ii) the increased use of reusable glass bottles, (iii) the use of on-site generated electricity from solar PV. The results show that all three CE strategies can lead to significant reductions in greenhouse gas (GHG) emissions, as well as other environmental impact categories. Applying the SCEIA framework shows to lead to useful results, even though challenges in its application remain. The impact results for the CE scenarios should be considered first estimations, and strongly depend on the underlying assumptions. Further research will provide more detailed impact results, and can advance the company's assessment maturity level by extending the inclusion of the social- and economic dimensions of sustainability.

Can Circular Economy (CE) Promote the Sustainable Development Goals (SDGs) and vice versa: Investigating the interactions between the CE and SDGs in the EU?

Mélissandre Houbeaut[1], Dilip Khatiwada[1], Anne Warchold[2], Prajal Pradhan[2]

[1]Division of Energy Systems, KTH - Royal Institution of Technology, Stockholm, Sweden. [2]PIK - Potsdam Institute for Climate Impact Research, Potsdam, Germany

Abstract

2015 is a turning point in the common history where the 2030 Agenda has set 17 Sustainable Development Goals (SDGs). The same year, the European Commission adopted its first Circular Economy Action Plan to be implemented with a concise milestone: closing the loop. This inspiring concept of shifting to a Circular Economy (CE) in opposition to a linear economy is now gaining tremendous attention worldwide in the light of the emergency of redesigning our society to accelerate the journey towards a sustainable development. This study scrutinizes the interconnections between the CE targets and the SDGs targets using unique pairs of indicator time-series from 2000 to 2019 for 28 member states of the European Union (EU). Firstly the correlations are disentangled into synergies for positive correlations and trade-offs for negative correlations using the Spearman's rank correlation. Secondly this study aims at going further in the interpretation by examining causality in correlations found through a Transfer Entropy (TE) model measuring the power of coupling strength for two possible causal directions: SDGs towards CE or CE towards SDGs. Broadly, the outcomes highlight a stronger causality in the interconnections in the direction CE towards SDGs and overall the results show more positive interconnections than negative ones. The highest share of positive impacts of the CE on the SDGs is found with SDG 7 (Affordable and Clean Energy), SDG 3 (Good Health and Well-Being), and SDG 15 (Life on Land). In contrast, the highest share of negative impacts of the CE on the SDGs is found with SDG 2 (Zero Hunger), SDG 9 (Industry, Innovation, and Infrastructure), and SDG 10 (Reduced Inequalities). Additionally, the study identifies various speeds of development between countries in the alignment of their SDGs progress and CE implementation. United Kingdom, Spain, and France gather the best results in term of positive interconnections, while Italy, Latvia, and Luxembourg appear to have the highest share of negative interconnections. To succeed in both commitments, identified synergies should be leveraged and trade-offs efficiently tackled.

Circular Value Stream Mapping (C-VSM): Rethinking production process in the agri-food sector

Florencia Kalemkerian[1], Dr. Javier Santos[1], Dr. Martín Tanco[2], Dr. Elisabeth Viles[1]

[1]TECNUN, University of Navarra, San Sebastian, Spain. [2]CINOI, University of Montevideo., Montevideo, Uruguay

Abstract

It is estimated that one-third of the food which is produced is lost or wasted as flowing through supply chains. Therefore, the Circular Economy (CE) constitutes a promising strategy to deal with food loss and waste by providing actions and solutions to reintroduce wastes into the production process. Although there are many frameworks proposed, the dominant interpretation of CE is mainly promoting a reductionist perspective, losing the idea of value creation through waste by rethinking the production process. Following this reductionist path, the green Value Stream Mapping (VSM) has been widely implemented in the production process to manage resources through the elimination of waste. Nevertheless, the implementation of this tool proves to be an efficient way to improve both operational and environmental performance in a linear production model.

However, the CE requires a new way of thinking. Therefore, reformulating the traditional green VSM to incorporate the principles of CE will constitute a powerful approach for companies to rethink the production process, and make a more sustainable management of resources. Since in the agri-food sector, there is a lack of simple and clear tools to analyze the production process under the lenses of the CE, the main aim of this paper is to present a circular-VSM (C-VSM) for this sector. Although some studies presented a C-VSM none of them redesign the traditional VSM, which is also another aim of this study.

To that end, a four-step methodology was followed. Firstly, a review of literature on circular strategies in the agri-food sector was conducted. Secondly, an initial tool was presented based on the input-output approach following the traditional scheme of the VSM. Then, a workshop with stakeholders from the sector was conducted to get new insights and therefore, revise, modify, and adjust the initial tool. Based on that, the final C-VSM was presented. Finally, as part of continuity for this work the tool will be tested in a company that produces artichoke. The C-VSM aims to easily identify opportunities for improvement that will guide companies towards a more sustainable way of production. The implementation of this tool consists of six steps: (1) system definition, (2) value flow description based on the input-output approach, (3) identifying opportunities for improvement, (4) identifying lean tools and circular strategies, (5) sustainability assessment, (6) developing the final C-VSM.

Based on the above mentioned, the results of this study are aligned with SDG 12: Sustainable Production and Consumption. Particularly with targets, 12.2 that focuses on achieving the sustainable management and efficient use of natural resources, and 12.4, which calls for an environmentally sound management of chemicals and all wastes throughout their life cycle, and 12.5 aims to substantially reduce waste generation. The originality of this work is that it presents a new tool to analyze the production process based on the idea of continuous improvement and rethinking these processes by focusing on value creation activities. Therefore, this study contributes to achieving sustainable development in companies, which is one of the main topics of this conference.

Colombian Consumers' Perspective on Circular Economy Paradigm for Attaining Sustainable Development

Dr. Luz Elba Torres-Guevara, M.Sc. Rafael Mora-Contreras, Dr. Andrés Mejía-Villa

Universidad de La Sabana, International School of Economic and Administrative Sciences, Chía, Colombia

Abstract

To contribute to the literature on sustainable production and consumption behaviour, this study aims to investigate the behaviour and adoption of CE activities by Colombian's citizens towards sustainable development. To achieve this goal, the study conducted a 16 items online questionnaire survey that investigate consumers' behaviours and attitudes, which was open from September 1st to October 15th, 2021. The sample consists of 1317 respondents and includes citizens from both genders with different education and income levels by age groups. The results show that more than 90% of consumers surveyed consider important to take care of the environment and carry out selective waste collection activities to produce new goods and prevent the depletion of natural resources. However, the percentage of respondents who carry out CE activities is very low, especially in mobility and the disposal of batteries and light bulbs at collection centres. It is also found that the number of consumers performing separate waste collection activities in households is still insufficient. In addition, a little more than half of respondents consider that the rental system compared to the ownership of goods represents a financial benefit; therefore, there is still much work to be done to transform the perception and purchase intention about circular business models.

Coming at the Circular Economy from Different Angles – a text-mining and contingency-based analysis of 3000 projects

PhD Josef-Peter Schöggl, MSc Lukas Stumpf, Prof. Dr. Rupert J. Baumgartner

Christian Doppler Laboratory for Sustainable Product Management, Institute of Systems Sciences, Innovation and Sustainability Research, University of Graz, Graz, Austria

Abstract

While the scientific literature exhibits an exponential growth of circular economy research, empirical studies based on large, global, and cross-sectoral samples are still scarce. To address this research gap, the study at hand analyses a dataset of 3015 circular economy implementation projects worldwide. The database was compiled by members of the Circular Economy Club (CEC), a non-profit organisation that connects CE professionals and organisations in 280 local clubs in 140 countries. For each of the 3015 documented projects, the CEC database describes the sector, the type of organisation, the country, and the main CE strategy followed. Utilising this data, the present study addresses the following two research questions. **(RQ1)** Do circular economy strategies significantly differ between sectors, types of organisations and countries? **(RQ2)** What are the main CE practices implemented in different sectors?

The first research question was answered using contingency and correspondence analyses of CE strategies, sectors, organisation types and regions. The results show that the CE strategy depends on each of these characteristics as indicated by significant chi-square tests ($p < 0.001$ in each case) and that the effect sizes are medium (0.34-0.41) based on corrected contingency coefficients. The correspondence analyses visualise the contingencies and allow interpretations.

To answer the second research question, the project descriptions were analysed using multiple correspondence analysis and hierarchical clustering applied to terms extracted from the descriptions using a natural language processing routine. More specifically, topical clusters are illustrated and compared for six sectors (manufacturing, consumer goods, fashion, food, cities, others) in general and per CE strategy (e.g. product life extension, waste as a resource, business model or design). The results underscore the statistical finding of significant differences between the sectors and substantiate it by detailing which specific CE practices are pursued in the different sectors and how they relate to the overarching CE strategies. For instance, while projects in the manufacturing sectors frequently focus on recycling, waste and process-related CE practices, projects in the consumer products sector focus more often on circular product design and, besides recycling, also on repair. Higher-order R-strategies are also found in the fashion sector, where besides recycling and recycled material use, also reuse is more often in the focus.

In summary, this study provides a comprehensive overview of the global CE engagement. It contributes to understanding how SDG 12 is approached in different regions and by different types of organisations. Among the eleven targets of SDG 12, insights are mainly provided regarding targets 12.2 on sustainable management and use of natural resources, 12.3 on halving food waste, 12.5 on substantially reducing waste generation and 12.6 on encouraging companies to adopt sustainable practices. Concerning the conference theme, the study particularly highlights the cultural dimension of sustainability as it compares the CE engagement of 50 different countries from all continents, providing space for mutual inspiration.

Exploring Circular Economy Criteria of EU's Taxonomy for Sustainable Activities

Dr. Sigurd Vildåsen

SINTEF, Trondheim, Norway. NTNU, Trondheim, Norway

Abstract

In August 2021, the EU Commission's advisory body launched the first draft of circular economy (CE) criteria for sustainable economic activities. This is part of a taxonomy scheme enabling Europe´s Green Deal, i.e. a policy to ensure net greenhouse gas emissions by at least 55% by 2030.

The rational behind the taxonomy is to classify which activities that substantially contribute to a CE in addition to doing no significant harm to other environmental objectives. Such a systemic perspective aims to minimise the risk of adverse effects on climate change and ecosystems when implementing CE strategies, e.g., recycling and reuse.

The manufacturing sector has been given a special attention in the Green Deal policies because of its essential role in production and consumption systems. This is evident in the proposed CE criteria from August 2021, and the research presented here aims to analyse the scientific foundation of the criteria while at the same time exploring implications for industrial contexts.

The scope of research is the activity called "Design, manufacture, remanufacture, and reselling of furniture" classified under NACE code C31 in accordance with the statistical classification of economic activities established by Regulation (EC) No 1893/2006. It includes manufacture of office and shop furniture, of kitchen furniture, of mattresses, and of other furniture.

Three specific CE criteria are addressed, namely A "Resell, refurbish and/or remanufacture furniture already used by a customer", B "Design and produce new furniture in a way that supports extended lifespan through durability, reuse, refurbish, repair and remanufacturing", and C "Design and implement a business model that extends furniture lifespan in practice".

The empirical grounding is based on three-year transdisciplinary R&D project owned and managed by a bed producer in Norway. Three suppliers and a reseller are involved in addition to a university and research institution. An exploratory research setting was conducted by introducing and discussing the three CE criteria in workshops and follow up conversations.

The findings point to the importance of circular business models (CBMs) as the cognitive frame of reference as well as tool for implementation of CE strategies. This is supported by a growing scientific literature on CBMs as an area within the larger CE debate. However, the taxonomy treats CBM development as a separate criterion somewhat detached from design, production, and marketing strategies which makes little sense from both an industrial and academic perspective.

A possible explanations for confusion around the CBM concept seems to be that the taxonomy emphasises product-as-service models, while the scientific literature adopts a much broader and nuanced perspective on CBMs. Thus, this research proposes generic clarifications and practical recommendations on how to apply the CBM concept in accordance with the systemic CE perspective adopted in the taxonomy, while securing a better scientific anchoring to the established CBM literature.

Flexible Circular Index for Responsible Cities

Pasqualina Sacco, Elena Rangoni Gargano, Alessia Cornella, Maria Aida Cavalera

Fraunhofer Italia Research Scarl, Bolzano, Italy

Abstract

Circular economy stands as a development model that combines competitiveness, innovation, and sustainability: a new vision of the economic system, taking an increasingly central role within governments, local institutions, and companies. In cities, circular economy plays a decisive role, as most of the resources produced are consumed there. Imagining a new development model for cities means envisaging it for the entire planet. In this perspective, a "circular city" must respond to a holistic view that combines technological innovation as well as economic, environmental, and social impacts.

The authors aim to map European best practices in the field of circular economy, identifying opportunities and barriers, as well as recognising actors and sectors involved. Moreover, the authors will outline the services offered by circular city models - in terms of infrastructure, training, financing - and citizens' need. From this analysis, the authors want to identify the actions needed for a circular economy model of cities and define a circularity index. In addition, tools used in other European cities that are effective in stimulating engagement with the territory, businesses and its citizens are presented.

To do this, the research will focus on the current state of Italy through an analysis of the maturity of Italian cities moving towards a circular model thanks to circular actions, new governance models, sharing economy, training, and awareness.

The authors' final objective is to define a flexible circularity index that can be customised according to the size of the city, the type of territory and the resources used. A first literature search was conducted by using Scopus and Web of Science for academic literature in different languages. Different combinations of key words were utilized and, considering the cross-sectoral nature of circular economy, no restrictions in the disciplinary scope of the journals were applied. Then, the search was extended on a conventional web search engine to include contributions non-Scopus indexed. This allows to have a more complete base of sources, given the evolving status of the topic.

This study, through a systematic literature review, becomes the place to reflect on the opportunities offered by circular economy models in Europe, considering their applicability and flexibility to define a responsible and sustainable territorial strategy. To achieve these results, scholars from different fields have been involved: from natural sciences to economics, philosophy, and social sciences.

In conclusion, cities are places where the contradictions of our modern life come to the surface. Contradictions that can only be resolved by using innovative shared and responsible solutions. To do this, our article aims to investigate not only the "classical" ecological, economic, and social dimensions of sustainable development, but also the ethical/cultural dimensions, which are considered crucial to unhinge the linear capitalist system and begin the transition to a circular system.

Considering the 2030 Agenda, the proposed excerpt refers especially to SDG 8 (Target: 8.2; 8.4), SDG 9 (Target: 9.1; 9.4), SDG 11 (Target: 11.3; 11.6; 11.7; 11.a; 11.b), SDG 12 (Target: 12.2; 12.5; 12.8) and SDG 13 (Target: 13.3).

How can the Financial Perspective Facilitate the Transition towards Circular Business Models? Insights from a literature review

Amal Kanzari, Fredrik Ingelsson, Josefine Rasmussen, Henrik Nehler

Linköping University, Linköping, Sweden

Abstract

Sustainable development has urged companies to change their way of doing business by transitioning from linear to circular business models (CBMs). Practitioners and academics have outlined financial benefits driving the transition, but also identified barriers hindering it. To facilitate the transition towards CBMs, there is a need to understand why financial barriers occur and how they hinder the transition. When transitioning to CBMs, companies generally pass through three innovation phases: ideate and design; implement and test; and finally, evaluation and improvement. Following these phases, managers and decision makers face challenges as they navigate against their usual practices. However, while a number of literature reviews have been conducted on CBMs, there is to the authors' best knowledge no review that holistically reviews the financial discussion and the financial barriers related to CBMs while simultaneously taking a transition process perspective. Hence, we aim to fill this gap. We provide a state-of-the-art of the field and delineate where more efforts are needed, providing detailed directions for future research, pinpointing required efforts for each phase in the transition process.

The systematic literature concerned papers published until fall 2020 and the final sample includes 25 papers published in 39 academic journals. Based on content analysis, these papers were grouped in three categories corresponding to the three transition phases. Financial perspectives including costs, revenues, performance indicators, risks and so forth were identified and coded.

The results show that there is a lack of financial studies in the early phase of CBM design. Predicting CBMs´ design outcomes is difficult due to their context dependency, the long-term perspective of the outcomes, and their dependency on market data. In addition, the design of the revenue model often happens after CBM implementation, which make it difficult to predict profitability. For CBM implementation, companies struggle with financing their new CBM and covering their upfront costs. CBMs experimentation is a solution for the implementation gap, however, there is a lack of empirical evidence on how to use experimentation to assess and predict the financial outcomes. CBMs are evaluated with a linear mindset, constrained by short-term reporting obligations and traditional accounting practices. Last, financial indicators, usually used in linear business model, are suggested both for prospective and retrospective evaluation. Nevertheless, there are no guidelines on how to use these indicators in the circular context. Based on this study, future research is therefore suggested to investigate how to develop financial forecasting capabilities and to deal with risk and uncertainties in long term perspective. Future work could also provide guidelines on the use of financial performance measurement for CBMs.

Through analyzing the financial barriers and suggesting future research paths, this study aims to encourage companies adapting sustainable practices and so contributes to SDG 12.6. It specifically contributes track 5.c Circular Economy, and sheds light on required efforts necessary to go beyond traditional practices, thus also contributing to the overall aim of the ISDRS conference.

Lessons on Extended Producer Responsibility in the Context of Circular Economy

Mr Kieran Campbell-Johnston[1], Dr Walter Vermeulen[1], Dr Sabrina Dermine-Brullot[2]

[1]Utrecht University, Utrecht, Netherlands. [2]UTT, Troyes, France

Abstract

Policy is a crucial driver for circular economy (CE) practices, creating a business baseline and direction. Many European Union (EU) policies focus on different aspects of production, consumption and waste processes. Current policies build on infrastructures and ideas that have developed and evolved over the previous 20 years relating to material efficiency and social and environmental protection from harm caused by waste processing. This presentation draws on the lessons and experiences from established CE policies and practices.

This presentation synthesizes the work and outputs of a PhD project that focuses on organizing and applying extended producer responsibility (EPR) in the context of CE in the EU and aims to reflect on the lessons learnt. EPR is a long-standing policy approach to product management, where post-user responsibility for a product is transferred to the original producer (of their representative) and away from local authorities. These systems have effectively promoted lower CE R-strategies (collection and recycling) through specified take-back requirements and obligations. However, the degree to which the decision-making processes and mechanisms for determining higher R-strategies, waste prevention and reduction can be improved remains a continuous challenge (both organizationally and theoretically). Drawing on the experiences and detailed case studies conducted in Italy, France and the Netherlands, this presentation presents the key observed weaknesses of the organization of EPR (nationally and globally) and reflects on potential pathways forward. The drive for CE and many sub-goals of the Sustainable Development Goals require a shift from recycling to more integrated decision-making processes. Such processes consider the responsible management of resources, waste reduction, prevention (SDG 12.2 and 12.5) and further operationalization of the cascading principle. These goals provide a broader perspective for this presentation.

Textile and Metal synergies: Two potential sectors for sectoral industrial symbiosis implementation in Portugal

Mr. Juan Henriques[1], Muriel Iten[1], Prof. Paulo Ferrão[2]

[1]Low Carbon & Resource Efficiency, R&Di, Instituto de Soldadura e Qualidade, 4415-491, Vila Nova de Gaia, Portugal. [2]IN+ Center for Innovation, Technology and Policy Research, Instituto Superior Técnico, University of Lisbon, 1049-001, Lisbon, Portugal

Abstract

Since 2004 Portugal has made important strategic and operational efforts to implement the Circular Economy. It has even promoted an ambitious, Plan of Action for the Circular Economy (PAEC), with the main objective of redefining the concept of the end of life of the linear economy, and promoting the concepts of reuse, repair and renewal of materials and energy. One of the most promising approaches for the implementation of the circular economy in the industrial sectors is Industrial Symbiosis (IS). This circular business model proposes symbiotic exchanges or synergies between companies that are developed in an industrial ecosystem.

The literature suggests that the manufacturing sectors are among the sectors with the highest potential for Industrial Symbiosis. In the strategic perspective of Portugal (PAEC), various priority sectors have been identified for the implementation of the circular economy in the Portuguese context, among these sectors we can highlight the textile and metal sectors. In Portugal, the metal (metallurgy and metalworking) sector was responsible, in 2017, for 7.9% of the turnover, and 5.7% of the jobs created in the national economy. On the other hand, the Textile and Clothing sector, represents a total of 19% of employment and 8% of turnover in the manufacturing industry.

In order to achieve this transition for a circular economy in the industrial sectors, it is necessary to address the potential sectors of the economy and identify their current status and potential for the implementation of this model. The main objective of this study is to characterize comprehensively the textile and metal sector within the scope of industrial symbiosis implementation, facilitating a database of substitution synergies between cross-sectorial supply chains. This characterization is based on enabling practices, implemented measures, and stream exchanges (wastes and by-products). The main results of this study are a comprehensive characterization of existent synergies in the two sectors (in a national and international) and the identification of the potential valorization scenarios for Portugal. The information presented in this study can be a useful tool for companies that intend to start sectorial and intersectoral symbiotic exchanges in those sectors since these results provide companies with efficient and understandable knowledge to promote their implementation, especially companies with a lack of background in industrial ecology.

Ultimate Producer Responsibility for e-waste Management - a proposal for just transition in the circular economy based on the case of used European electronic equipment exported to Nigeria

Mr Kaustubh Thapa[1], Dr. Walter Vermeulen[1], Dr. Pauline Deutz[2], Dr. Olawale Olayide[3]

[1]Copernicus Institute of Sustainable Development, Utrecht University, Utrecht, Netherlands. [2]Department of Geography, Geology and Environment, University of Hull, Hull, United Kingdom. [3]Department of Sustainability Studies, University of Ibadan, Ibadan, Nigeria

Abstract

European secondhand electric and electronic equipment are imported to Nigeria. Although e-waste imports in Nigeria are illegal, research shows it is an ongoing practice through various loopholes. These exports from Europe and imports in Nigeria have sustainability and circularity implications for both. Collaborative actions between Nigeria and European Union is essential for a more circular and fair export and import of secondhand products with consideration for value-adding, value-retaining and curbing illegal e-waste exports. Using a transdisciplinary approach, we identify existing practices and challenges and co-create actionable solutions towards a more sustainable, circular e-waste management in Nigeria and towards a just export/import relationship between Nigeria and the European Union. Seeing the multiple-use cycle of electronic and electric equipment in multiple countries, we show the limitations of national or regional extended producer responsibility and propose a more inclusive and internationally functional ultimate producer responsibility. Using our findings, we reason why ultimate producer responsibility is essential to achieve: i) a just transition in the European circular economy considering the international dimension and ii) for countries like Nigeria who already have or are designing extended producer responsibility but also rely heavily on the imports of secondhand products.

Abstract

In the last 20 years, the development of biorefineries has been increasing around the world. This increase is mainly due to the potential benefits presented by this type of plant, namely, the reduction of raw materials, reduction of operational costs, and its adaptability that allows valorization of diverse feedstocks. Nevertheless, the implementation of biorefineries still faces some significant challenges such as appropriate availability of raw materials (quality and quantity), feasibility in the product supply chain, economies of scale, and the difficult territorial anchoring. Some of those problems are related to the current approach taken to implement biorefineries that frequently lay in the perspective of developing a large-scale plant under a single large-scale investment. An interesting approach to solve some of those problems is the introduction of the agility concept in biorefineries, i.e. the promotion of agile biorefineries (AB). Agile biorefineries are flexible plants, where a reconfiguration of the process is achieved by switching equipment inside a single standalone plant, therefore they achieve this agility by adapting configurations, varying feedstocks, and even changing operating conditions throughout time. Despite relevant efforts that have been made to promote a definition of agile biorefineries, the authors consider that it is still necessary to contribute to a common definition of this concept by identifying its main characteristics, which have not been clearly established. This study has two main objectives, firstly to contribute to the common definition of the AB concept and the identification of its core characteristics. Secondly, to identify the key factors in the process of implementing an Agile Biorefinery. To achieve these objectives, this study is based on a mixed approach that joins a systematic literature review with expert consultation. The main results of this study are: (i) contribution for the common definition; (ii) identification and description of the fundamental characteristics of an agile biorefinery; and (iii) a framework of key factors (enablers and challenges) in the implementation

process of AB. The results presented in this paper could be a valuable tool for stakeholders that intend to implement agile biorefineries, especially for those who have no previous experience in this area.

Keywords: Agile bio refineries, agility, circular economy, key factors.

1. Introduction

In recent years the implementation of biorefineries has increased in the world. One of the most accepted definitions of biorefining was given by the International Energy Agency defining biorefining as "the sustainable processing of biomass into a spectrum of marketable products and energy" (Bauer, Coenen, Hansen, McCormick, & Palgan, 2017). The IEA Bioenergy also defines bio refineries as "the sustainable processing of biomass into a spectrum of marketable bio-based products (food/feed ingredients, chemicals, materials) and bioenergy (biofuels, power and/or heat) Factory (Ree & Jong, 2019).

The implementation of biorefineries presents several benefits in various areas such as environmental, social, and economic. Among these benefits are reduction of raw materials, reduction of operational costs, and its adaptability that allows valorization of diverse feedstocks, among others. Nevertheless, the implementation of biorefineries still faces some significant challenges such as appropriate raw material availability (quality and quantity), feasibility in the product supply chain, economies of scale, and difficult territorial anchoring. Despite the increase in biomass processing projects and initiatives over these last two decades, the development of biorefineries is significantly slowed down because of several constraints (Houngbé, Barthe-Delanoë, & Négny, 2019).

A promising approach to overcoming these challenges and promoting biorefineries is the implementation of agile biorefineries (Houngbé et al., 2019). Agile biorefineries have been defined as flexible plants, where a reconfiguration of the process is achieved by switching equipment inside a single standalone plant, therefore they achieve agility by adapting configurations, varying feedstocks, and even changing operating conditions throughout time.

The current approach to biorefining is through a large-scale plant under a single large-scale investment. However, this appears to be a difficult approach to replicate. The new cases and associated process technologies of de-constructing and re-constructing biological feedstocks allows us to design and build new, lower cost, agile bio-refineries that can take in a variety of inputs and create a variety of outputs. Rather than a single, large-scale plant dedicated to a specific waste stream, we now imagine a set of independent manufacturing plants that can collaborate and compete to maximise the total value (economic, environmental & social) of a waste stream. Furthermore, there are no existing examples of agile bio-refineries globally and our research seeks to make the first step towards identifying key parameters and requirements for the creation

of an agile bio-refinery, as well as outline the key barriers that need to be overcome by industry and wider society.

This study has two main objectives, firstly to contribute to a common definition of the AB concept and the identification of its core characteristics. Secondly, the paper aims to identify key factors involved in the process of implementing an Agile Biorefinery. In order to accomplish these objectives, the paper poses the following research questions:

RQ1: What is a common definition of an Agile Biorefinery and what are the fundamental characteristics of an agile biorefinery?

RQ2: What are the key factors (enablers and barriers) in the implementation of AB?

This paper is structured into four sections, a first and an introductory section for the approach and objectives of the research. A section to present the methodology followed in this study. A result section to present the common definition of AB, main characteristics, and implementation key factors. In the last section, conclusions are drawn.

2. Methodology

Research strategy

The first step in this study was to define methodology research that would allow the achievement of the proposed objectives. Figure 1 represents the proposed methodology.

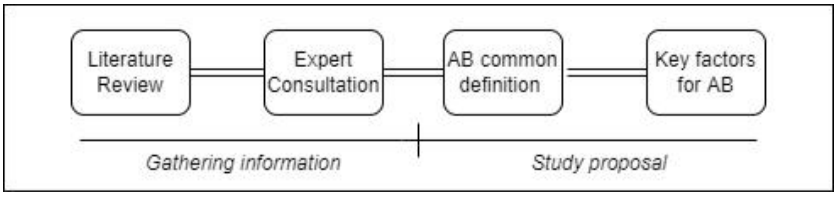

Figure 1 Levels of the literature review

This study adopts a research strategy that combines a literature review and expert consultation to identify a common definition for AB and the key factor in its implementation process.

Literature review and expert consultation

The objective of the literature review is to reveal the common trends between AB and other concepts (such as biorefineries, modular biorefineries and integrated biorefineries) (i); the possible enablers and barriers within

the scope of AB (ii); and the contribution of other concepts to AB (iii). A search was conducted in the search engines Scopus and Web of Science on three different levels. Figure 2 shows the different levels of the literature review with the subject addressed and the number references identified.

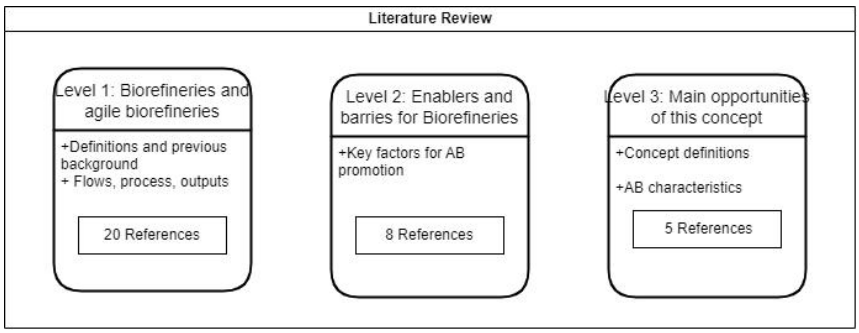

Figure 1 Levels of the literature review

Our main information source for the case studies characterization was based on scientific peer-reviewed journal articles. A complementary search was also developed through Internet searches for technical reports and technical documentation of European initiatives, such as European projects and reports. In addition, an expert consultation was performed.

In parallel to the literature review, an expert consultation was designed and performed. In this process have been interviewed 3 experts related to the field of implementation of bio refineries. The three experts selected have a similar profile, with a strong technical background in the practical implementation of biorefineries. This consultation was performed through an interview of approximately one hour. In this interview we address 4 main topics: the concept proposal for AB (i), the main characteristic of AB (ii); key factors for the AB implementation process (enablers and barriers) and the main opportunities of this concept. This consultation enabled the identification of critical aspects that were not registered in the scientific literature and provided important insight for our research.

Identification of key factors

Once the common trend and concept of agile biorefineries were identified, the next step in the research was to identify the potential key factors involved in the implementation process of agile bio refineries. For this purpose, the identification of enablers and barriers (Key factors) was developed through a methodology of 3 sequential steps to identify which were the enablers and barriers associated with the AB concept:

- Identify key factors in the agile bio refineries. Establish a state of the art in key factors regarding similar concepts (For instance Bio refineries and modular bio refineries)

- Use expert consultation as a gathering information method
- Use comparative analysis in order to identify the key factors for AB

3. Study Results

A common definition for Agile Bio refineries (AB)

Taking into account the previous background in the definition of agile bio refineries and the inputs of our research, the authors consider that an AB is a flexible plant, where a reconfiguration of the process is achieved by switching equipment inside a single standalone plant, therefore they achieve this agility by adapting configurations, varying feedstocks, and even changing operating conditions throughout time.

In this sense agile restorative biorefinery involves a relatively low capital investment modular (adaptable) facility, deployed locally (uses local, short-distance available resources), capable of utilising different feedstocks (flexible), including wastes, in a small-scale but high yield production, which works in tandem and focusing in generating value across all stakeholders. In the following section, the core characteristics will be addressed.

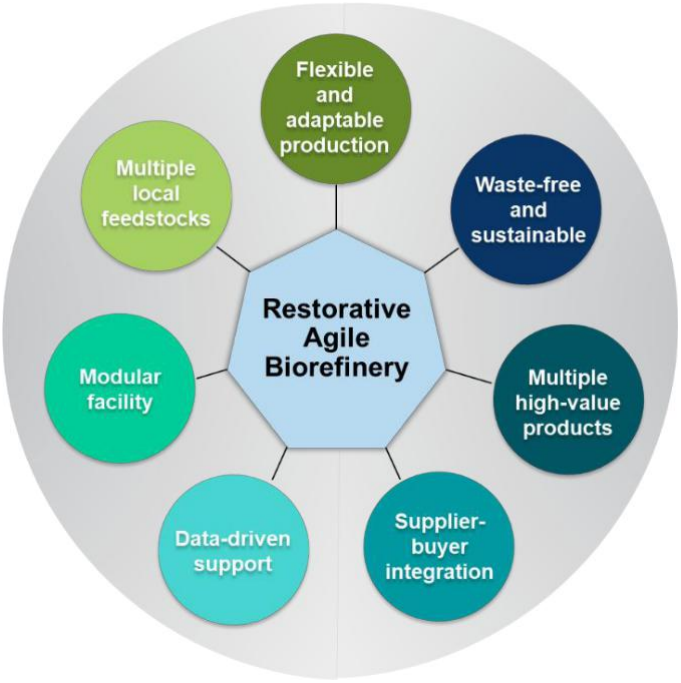

Figure 3 Restorative agile biorefinery concept characteristics

Flexible and Reconfigurable

From a manufacturing standpoint, flexibility attains the capacity of how fast the company converts its process(es) from making an old line of products to producing a new product. Early definitions are based on the notion of adaptability to uncertainties (ElMaraghy, 2005), which still retains much of the essence given to flexible manufacturing systems. The ability to change a production schedule, modify a part, or handle multiple parts. The ability to rapidly increase or decrease production levels of shift capacity from one product to another. The reconfigurable manufacturing paradigm was introduced as a necessity to cope with relatively large fluctuations in product demand and mix caused by market disturbances (Koren et al., 1999).

To successfully construct the concept of agile biorefinery, one must take these factors into account and consider their integration into the design, planning and operational management of biorefineries. Biorefineries need to be designed for flexibility so that they can adapt easily to changes in feedstock supply and/or demand for value-added products (Villemont et al., 2017).

Feedstocks and technology selection for agile

A biorefinery is typically defined by the type of feedstock and conversion process applied (Ubando, Felix, & Chen, 2020). The first-generation feedstocks are already very compromised due to global food supply shortages and have been reported to increase the prices of food and animal feed (Sims, Mabee, Saddler, & Taylor, 2010). This tendency is being aggravated by the climate crisis and increased human population, thus not allowing concomitant use for sustainable biorefining.

In this sense, the authors consider that efforts should be directed towards non-food competing feedstocks, which means using biowastes and by-products from several agro-food and non-agro-food sectors in cross-sectorial exchanges. Among those, stream materials such as lignocellulosic materials, green fertilizers, and other farm residues, kitchen waste, agro-food waste, industrial waste, and forestry wastes can be highlighted (Naik, Goud, Rout, & Dalai, 2010). A waste biorefinery is said of capable producing fuels, power, heat, and value-added products (Nizami et al., 2017). For example, the use of lignocellulosic materials allows different platforms to be deployed for the extraction of intermediate products such as lignin, and hemicellulose, which could be further processed for value-added products such as bacterial cellulose, biopolymers, and bio solvents (Takkellapati, Li, & Gonzalez, 2018). Consequently, these have several uses by different industrial sectors such as the medical, pharmaceutical, textile, chemical, among others.

To take advantage of the relatively low processing capacity (due to scale), the production system needs to be highly efficient in terms of value-added. The production processes and thus, technology selection needs to be carefully selected, to allow the production of high-margin products at minimal resource use. There are reports

of reduced capital costs in these integrative multi-productive systems (Olguin-Maciel, Singh, Chable-Villacis, Tapia-Tussell, & Ruiz, 2020), and of effectiveness in maximising biomass yield and efficiency (Pinales-Márquez et al., 2021). Not all technologies are appropriate for agile biorefining, and consequently, a key design requirement is to effectively optimize chosen supply (raw material) and the portfolio of products to be produced. The biochemical pathway seems promising from a small-scale and low-cost standpoint (Igbokwe, Ezugworie, Onwosi, Aliyu, & Obi, 2022). Several studies also consider the use of biomass fractionation technologies to optimize efficiency (Sun et al., 2018; Xu et al., 2020).

Small-scale, modularity and decentralisation

Larger centralized processing plants benefit from economies of scale due to reduced marginal costs, better processing yields, and returns on investment. For these reasons, small-scale processes greatly defy economies of scale. However, (Bruins & Sanders, 2012) argue that economies of scale may not be as important in the biomass-based sector as it is in fossil-based sectors due to the sparsity of biomass energy density and reduced cost of technology.

Some of the advantages of small-scale processes are outlined in terms of reduced transportation costs through the use of local resources, farmer benefits, storage, and logistical ease, and better capabilities in re-using waste and heat (Bruins & Sanders, 2012). These are expected to have lower initial investments and operational costs, lower energy requirements, and less capital-intensive technology (Susmozas, Moreno, Romero-García, Manzanares, & Ballesteros, 2018).

Small-scale biorefineries are typically deployed locally (near feedstock sources) and in rural areas. This contributes to the decentralization of the processing chain and possibly establishes deeper collaboration bonds with farmers and suppliers of biomass. It is this alignment and close cooperation that enables the agility capabilities of the system (company, supply chain).

The single large-scale facility can be split into several smaller ones by leveraging local sources of feedstock and creating an interconnected network of biorefineries. Using distributed manufacturing to promote decentralization by addressing location and scale in terms of technology, processes, systems, and business strategies (Vladimirova et al., n.d.). Collaborative approaches may facilitate production escalation by downstream integration and processing of flows (Günther et al., 2014).

The modularity comes into play as several production units can be added to up-scale the production process as needed, and removed, to de-scale the process. Designing a modularity system may favour agility by implementing several singular low-cost but highly effective modules (Bramsiepe et al., 2012). These modules

can be (re)deployed depending on the locally available biomass and contain new conversion processes adapted to the product being produced. This can be linked with the micro-factory concept which integrates automatised production of customised products, delivered on-demand, in which capacity is increased by embedment in a network with other micro-factories (Okazaki, Mishima, and, & Ashida, 2004).

Role of IoT and Information Technologies

Information technologies are fundamental tools for agile systems, as it allows the integration of processes, technology, people, and organizations (Gunasekaran, 1999). Those technologies promote the creation of virtual-based systems, essential for deepening supply-buyer collaborations, and forecasting and satisfying market demands. An agile biorefinery urges to be in constant awareness of the state of the supply given its scale and localized production. Data analytics and the use of I4.0 to sustain and validate operations are likely to have a significant role in streamlining the biorefinery supply chain and operations and optimising purchasing and production activities.

A good example of these synergies is the HereWear H2020 project ("HereWear: Bio-based local sustainable circular wear," 2022) which works exactly in integrating digitalised production at a local scale for on-demand textile production and clothing goods. It may have a glimpse of what is required to successfully integrate and transition to agile and restorative biorefining.

Key factors for Agile biorefineries: enablers and barriers

Since the literature diverges in the definition of key factors, two concepts that limit the boundaries of the enablers and barriers have been followed. An enabler is a factor that facilitates and supports the concretization of symbiotic synergies. On the other hand, a barrier is a factor that hinders or obstructs the development of symbiotic synergies (Henriques, Ferrão, Castro, & Azevedo, 2021). Enablers and barriers can be presented in various dimensions and levels. For the purpose of this study, five fundamental dimensions have been suggested where the enablers and barriers can take place. These fundamental dimensions are policy & regulation, environmental, social, business, and logistics & management.

Main enablers for AB

Regarding the identification of the enablers, our results present 10 different enablers, distributed in 4 fundamental dimensions (environmental, social, business and logistics & management).

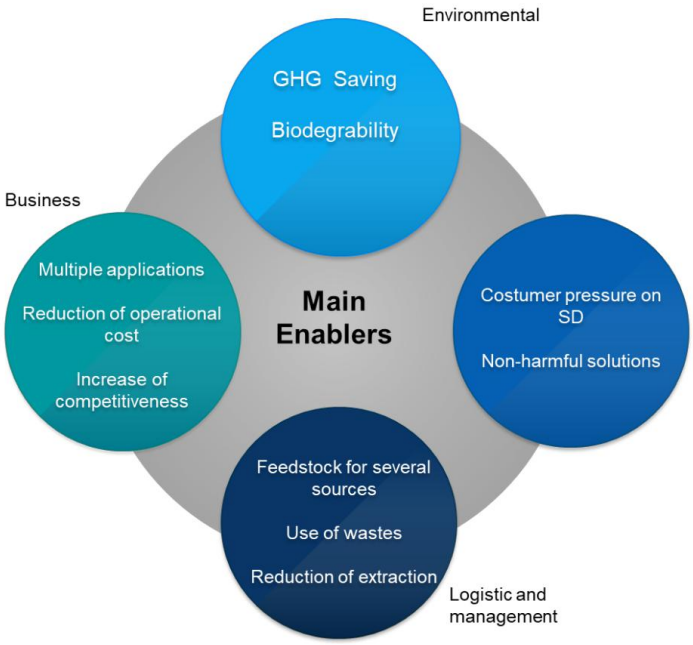

Figure 2 Main enablers for Agile bio refineries

Business

Among the main enablers that can be highlighted in the business category for agile biorefineries, is the multi-applicability that this plant will have. Since, due to the nature of the proposed concept, these plants can process and value various streams/ feedstock and convert them into biofuels, fuels, energy, and other products, thus presenting multiple applications (Ghatak, 2011). One of the main motivations that drive the increase in the promotion of biorefineries in recent years has been the ability to generate income and reduce costs that this type of unit presents. It is expected that the AB also has the potential to reduce operational costs such as feedstock cost reduction and also has the ability to create value through the development of high value products (Lane, 2020). Another fundamental aspect of this dimension is the increase in competitiveness since, similar to biorefineries, the competitiveness of this plant is based on the balance between the production of bio-products and bio-materials of high value/low volume and high volume/low biofuels value (LNEG, 2019).

Environmental

In the environmental dimension, the main enabler presented is the contribution to the reduction of greenhouse gas emissions (GHG), for the reduction of organic waste deposition in landfills. Nevertheless, there are other GHG saving opportunities, for instance, GHG saving associated to the production of heat and electricity and other bioproducts (LNEG, 2019). On the other hand, another important factor is the high biodegradability of potential feedstocks to be valorized. Those biomasses are generally low or non-toxicity, and biocompatibility,

not causing risks to the environment and animals, plants, and humans, which increases their potential to be used in various products.

Social

The growing consumer awareness and especially the custumer pressure on sustainable development are one of the major enablers in the social. A growing consumer preference for 'green' products is observed, coupled with a growing awareness of the need for action regarding carbon emission reduction (European Commission, 2021) (European Commission, 2019). Another relevant enabler in this regard is the non-harmful solution that this plant presents since Bio-based chemicals are sometimes considered non-harmful, and non-toxic since they originate from nature. Some bio-based solvents are non-toxic and harmless.

Logistics and management

The use of feedstock from several sources, such as agro-food and non-agro-food sectors in cross-sectorial exchanges (Lignocellulosic materials, green fertilizers, and other farm residues kitchen waste, agro-food waste, industrial waste, and forestry wastes) represent a major enabler for AB. The use of waste, reduction of GHG emission, and reduction of raw materials extraction also represents a considerable advantage.

Main barriers for AB

Regarding the identification of the barriers, our results present 10 different barriers, distributed in 4 fundamental dimensions (Policy & regulations, social, business, and logistics & management).

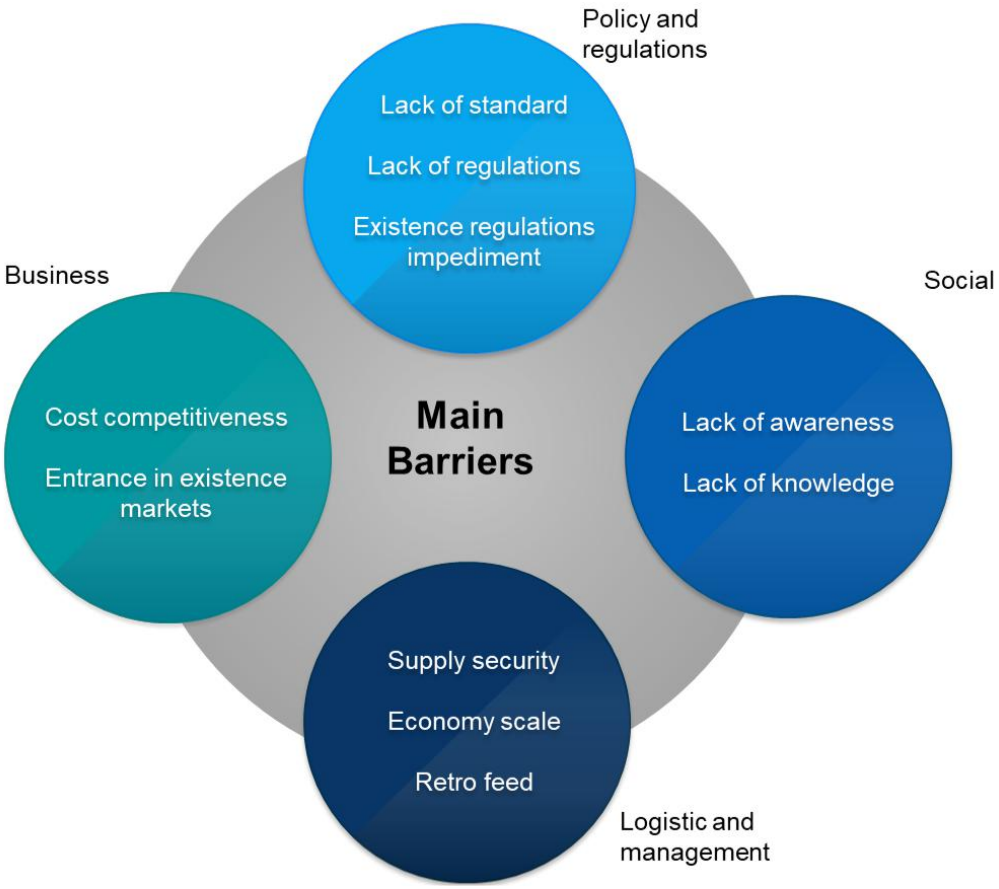

Figure 3 Main challenges for Agile bio refineries

Business barriers

Concerning business barriers, the lack of cost competitiveness for some EU countries due to higher labor costs affecting CAPEX and OPEX, higher taxes, higher energy costs, and limited low cost biomass feedstocks compared to some other regions in the world, is one of the major barriers in this category (Charles et al., 2013; European Commission, 2021). Another issue emerges is the entrance in existing markets since many of the potential feedstock are already valorized locally or are directed to waste management and landfilling.

Policy and regulations

Among the main regulatory barriers that various countries face in the implementation of biorefineries is the lack of standards and lack of regulation (European Commission, 2021), which ends up hindering the appropriate promotion of these plants, especially in the initial phase (planning and creation). The result of this study suggests that ABs face similar impediments due to the nature of the concept.

In the same line of thought, one of the problems that we consider will be common in the promotion of these plants, is the existence of regulations, which are an impediment to the recovery of wastes (Ladu, 2018). The waste streams usually have a non-uniform classification, due to the diversity of materials such as waste, residue, or coproduct. This fact leads to loopholes that cannot be addressed by national legislation alone. The ABs will function from the recovery of various feedstock, many of which will be classified as waste. We foresee similar regulation barriers to those faced by other models such as industrial symbiosis and the circular economy in the industry.

Social

Since the concept of AB is still new, our research suggests that in the initial phases of promotion, a major barrier is the lack of knowledge and awareness especially in the benefits that this plant can produce (economic and environmental benefits), especially by SMEs. On the other hand, the lack of technical knowledge and technical expertise required to develop AB will be an important barrier to overcome in this process.

Logistics and management

All bio-based product pathways, to varying degrees, have near-term concerns about feedstock supply and mid-long term concerns over feedstock availability (European Commission, 2021). One of the major concerns that emerge in this dimension is the supply security due to the variability of the availability.

4. Discussion and conclusions Discussion

Regarding the first research question that refers to the common definition for AB, the paper achieves a contribution to the common definition of AB and identifies the fundamental characteristics of AB. The authors achieved a first draft of a common definition for AB and its main characteristics. The authors consider that Agile biorefineries are flexible plants, where a reconfiguration of the process is achieved by switching equipment inside a single standalone plant, therefore they achieve this agility by adapting configurations, varying feedstocks, and even changing operating conditions throughout time. An agile biorefinery involves a relatively low capital investment modular

(adaptable) facility, deployed locally (uses local, short-distance available resources), capable of utilizing different feedstocks (flexible), including wastes, in a small-scale but high yield production, which works in tandem and focusing in generating value across all stakeholders. Seven characteristics of AB were identified, namely: Multiples local stocks (i), Flexible and adaptable production (ii), waste-free (iii), multiple high-value products (iv), supplied buyer integration (v), data-driven support (vi), and modular facility (vii).

Regarding the second research question that refers to the key factors in the implementation process of AB, through our research 10 enablers and 10 barriers were identified that could potentially appear in the implementation process of agile biorefineries. These 20 key factors are distributed in various fundamental dimensions such as Policy & regulations, environmental, social, business, and logistics & management.

Conclusion

An agile biorefinery is a biorefinery that is built to strive in an uncertain environment, benefitting from small-scale localized production with easy to implement technologies that are feedstock flexible. Working in a small-scale environment requires a closer connection between the sourcing of materials and wastes and the production steps at the biorefinery. A network of localized biorefineries is formed through information systems and integrated with downstream industries for the concomitant production of value-added products and biofuels on a global scale.

This paper achieves the first common definition of this concept that was built by the main characteristics addressed. In the second part of the paper, the key factors (Enablers and barriers) for the implementation process of AB were identified and addressed.

Without disregarding the results obtained in this study, we consider that this study had some limitations due to its nature. The definition of AB, fundamental characteristics, and key factors was based on methods such as observation, literature review, and expert consultation. The authors consider that a real case validation will strengthen the results presented in this study.

Abstract

Industrial activities are responsible for most of the use of natural resources and the generation of waste. 50% of greenhouse gas emissions are attributed to the production of materials and products. The circular economy (CE) has been established as a model that can change the way we produce products by cycling back materials as a route toward the recovery of waste. Implementing projects efficiently using resources in a system can be helped through governance tools that evaluate and facilitate a transition. The Transition Management (TM) framework can be used as an analytical approach that contributes to governing such transition. This framework aims to influence, facilitate, stimulate, and organise processes that contribute to the transition towards a circular model. The objective of this study is to analyse how the transition to a CE is developing since the emergence of industrial symbiosis (IS) in the Humber region. The study seeks to describe the main features that allow the region to make progress towards a CE, whether there are some stakeholders essential to this process, and to analyse whether the activities initially implemented are still relevant to transition towards a CE. The region was examined through a qualitative case study. The case was constructed and analysed through two types of data: documents and interviews. The document review included desk research of the Humber region to establish an understanding of CE strategies. The semi-structured interviews were carried out with stakeholders providing insight into how this region approaches CE as well as the activities that are currently taking place. The data was analysed under the TM theory approach. This was done through the MAXQDA software for qualitative and mixed methods research. The data collected gave an overview of how the industrial strategies used to operationalize IS in the Humber Region are transforming towards a CE system. The results would serve to refine the TM methodology framework by understanding the dynamics of this context that might help to frame the process conditions needed to transition towards a CE system through IS.

Keywords: transition management, industrial symbiosis, circular economy, sustainable development, case study.

1. Introduction

Industries are substantially responsible for the world's resource usage and waste creation and are hence liable for contaminating and damaging the environment (Prieto-Sandoval, Jaca, Santos, Baumgartner, Ormazabal, 2019). Nonetheless, industrial systems have sought to attain sustainability through various modifications and reformations, such as resource optimization at the input stage and good waste management at the output stage (Gopinath, Bahurudeen, Appari, & Nanthagopalan, 2018). Thereby companies have tried to convert materials that would otherwise turn into waste at the end of their lifetime, into resources for other companies (Prieto-Sandoval et al., 2019) or processes (Velenturf, A. 2017a) to reach a (CE) model.

This CE model incorporates IS. While CE aims to reduce resource input into the economy and to keep products and materials in use for longer, IS focuses on turning wastes and by-products from production processes into resources for other industries. IS is considered a useful strategy for supporting the transition from a linear to a CE model (Abreu & Ceglia, 2018; Merli, Preziosi, & Acampora, 2018; Prosman, Wæhrens, & Liotta, 2017). IS-related circular models have developed on self-organised, facilitated, planned models various paths in China and Europe, which account for the majority of case studies of applying solutions to create these systems (Rincon-Moreno, Ormazabal, Álvarez, & Jaca, 2020). Countries in Europe have developed secondary materials markets that can compete and minimize reliance on primary resources (European Commission, 2015; McDowall et al., 2017; Zink & Geyer, 2017).

However, one of the problems related to an extended IS adoption is explained by Petit, Sablayrolles, & Yannou-Le Bris (2018) as the impediment to incorporating organisational perspectives with other components of IS (e.g. material flow analysis) due to a higher focus on IS adoption more related to technicalities (Cerceau, Mat, & Junqua, 2018). So far, a large proportion of research treats technical aspects (e.g., supply chain, waste, energy, emissions), whereas aspects that might deal with collaboration with different stakeholders such as information, sustainable development, and networks are not being treated equally as a typical topic in an IS (Abreu & Ceglia, 2018). Authors such as Mortensen & Kørnøv (2019) have similarly stated that one of the critical factors in IS adoption lies in organising this process to establish synergistic relations and initiate partnerships.

Moreover, regardless of existing technical suitability and potential financial and environmental gains obtained in implementing IS (Doménech & Davies, 2011), scaling it up would require extensive collaboration with industry and other stakeholders (Velenturf, A. 2017b). So, moving away from a linear model goes beyond turning waste into valuable materials, including a deep knowledge and understanding of relevant stakeholders (Hein et al., 2017a). This creates obstacles to a systemic IS adoption, hence it is vital to define what type of strategy would bring together diverse stakeholders to implement this solution.

To address this type of systemic flaw, changes must be fundamentally restructured via transitions. Transitions are defined as "processes of structural change in social sub-systems" that occur when dominant structures are put under strain, either by external changes or through an endogenous innovation process to offer direction for the wicked challenges that we are presently confronted with (Peterson, Baker, Aggarwal, Boyer, & Chan, 2021). Since industries are fairly liable for depleting resources, they are critical in playing a significant role in social transitions between the corporate environment and the larger environment to create a sustainable production model within a society (Bidmon & Knab, 2018). So, CE can be considered as a unified socio-technical system involving the change of industrial processes, with IS serving as a pillar to become the dominant industrial system used by many countries (Schot & Kanger, 2018).

Loorbach & Wijsman (2013) have recommended further research into this societal viewpoint of business as a driving factor in addressing social and environmental challenges. This insight has fuelled research into new kinds of governance, which have been generally labelled as TM or transition governance. The word "management" is derived from an overtly normative orientation of sustainability: specifying where we want to be, what should be done, and how it should be done (Peterson et al., 2021).

Therefore, the purpose of this study is to integrate and use concepts and learnings from the emerging area of TM to systematically investigate how to shift from a linear system to a more sustainable mode of production. To that end, the paper's specific objectives are as follows: a) apply concepts from the TM literature to past transitions in the Humber Region in the UK to develop a conceptual framework for TM of IS systems; (b) describe the main features that allow the region to make progress towards a CE, whether there are some stakeholders essential to this process to explore future transitions; and (c) analyse whether the activities initially implemented are still relevant to transition towards a CE. The structure of the paper covers a literature review, methods, and results consecutively, concluding with a framework that proposes how to create spaces for experimentation and collaboration, how and which actor networks to mobilise, and what action strategies to recommend implementing. These insights could then be applied to other regions in developed and developing countries, to avoid becoming entrenched in unsustainable management as they expand industrial outputs.

2. Literature review

Industrial Symbiosis

IS enforces an approach that takes inspiration from how industrial systems mimic natural ecosystems, and it can simulate the distribution of materials, energy and information flows (Mallawaarachchi, Sandanayake, Karunasena, & Liu, 2020). IS aids in the transition to a CE by minimizing dependency on virgin resources

(Abreu & Ceglia, 2018; Nasir, Genovese, Acquaye, Koh, & Yamoah, 2017; Saavedra, Iritani, Pavan, & Ometto, 2018). For example, China's CE growth is built on policies that aim to construct a broad supply chain through regional industrial parks aimed at CE development (Fraccascia, Giannoccaro, & Albino, 2019; Mathews, Tan, & Hu, 2018). In the European Union, on the other hand, the circularity in production processes is focused on building secondary materials markets to minimize reliance on virgin resources, which has helped the expansion of IS efforts in some countries (Bassi & Dias, 2019; Petit-Boix & Leipold, 2018).

The European Commission (EC) considers that circularity in production processes has the potential to produce significant material savings throughout value chains and industrial processes, as well as generate additional value via the facilitation and implementation of IS (European Commission, 2020). As a result, the EC has set a new action plan to boost circularity in production processes at the supra-national level (European Commission, 2020). By doing so, the EC contemplates circularity in production processes as a critical component of a broader industrial transition toward net-zero goals carbon neutrality and long-term competitiveness.

However, despite the efforts of the EC to promote a CE, only a few nations in Europe are following CE concepts in which IS now plays an important role that may be regarded as effective in tackling the difficulties of CE according to the European Union criteria (Mazur-Wierzbicka, 2021). The expansion of IS has been discordant in Europe due to enacting policies at the country level, allowing the proliferation of IS activities in only certain countries (Bassi & Dias, 2019). Moreover, IS remains a niche approach with several obstacles (e.g., legal, legislative, and financial impediments, organisational concerns) (Ormazabal, Prieto-Sandoval, Puga-Leal, & Jaca, 2018) and has been embraced in a some industries (Brown & Bajada, 2018; Cramer, 2020a; de Jesus & Mendonça, 2018).

As a consequence, IS deployment in some industries is unknown, despite being demonstrated as a potential strategy to promote the CE transition (Yu, Yazan, Bhochhibhoya, & Volker, 2021). Most of the reasons for lagging in implementation are attributed to a hesitant industry ecosystem willing to embrace the transition (Kirchherr et al., 2018). Likewise, experimental cases demonstrating implementation are not a widely extended practice (Kalmykova, Sadagopan, & Rosado, 2018). Such a low level of implementation is a drawback to the advancement of CE (Panwar & Niesten, 2020). According to Abreu & Ceglia (2018), implementing CE through IS initiatives is critical to engaging corporate and non-business actors to achieve complex synergies. Collaboration amongst stakeholders such as enterprises, governments, and institutions to enable the transition can support solutions from an IS viewpoint (Saavedra et al., 2018).

Transition Management

The literature has recently reported adopting a system perspective rather than firm perspectives to implement IS business models focused on the system's governance and the stakeholders involved that made up that particular circular system (Fraccascia et al., 2019). This focus on a system perspective helps to understand how IS firms are incentivised, motivated, or forced to change through the various mechanisms and how different stakeholders' interest needs to be studied in future research within their context (Yuan, Evans, Wen, & Ma, 2019). Transitions research offers insights to mobilise transformative capabilities from the current system toward a more sustainable production and consumption system known as socio-technical systems (Geels & Schot, 2010). The results obtained during the transition process can be upscaled to the mainstream level starting from the strategic level to a more operational one (Elia, Gnoni, & Tornese, 2020; Jurgilevich et al., 2016).

Loorbach, Frantzeskaki, & Avelino (2017) suggest TM research as a proxy for a deliberative process to accelerate change through a shared strategic vision. TM is a multi-actor process including stakeholders from many socioeconomic groups such as government, non-governmental organizations (NGOs), businesses, academics, and intermediate organisations. The fundamental aspect of TM is to facilitate transitions by gathering stakeholders to develop a cooperative instead of a competitive relationship (Köhler et al., 2019). Through constructive conversations, they conceive, negotiate, and discuss to change their understanding of and attitude to challenges (Dóci, Rohracher, & Kordas, 2022).

The elements of the TM framework distinguish four levels: arena, agenda, experiments, and monitoring (Figure 1). This process contains four management tasks that may not occur in sequential order but might occur in parallel with a continual back and forth between them. These components or transition fields can help solve societal processes, persistent problems, fundamental change, and innovation processes such as the challenge to create circular systems. Likewise, the TM framework provides a set of tools that develop transition-based governance strategies, including a broader range of governance instruments (Loorbach et al., 2017).

Figure 1 *Transition management framework*

The four levels of the framework are explained below (Loorbach & Wijsman, 2013):

- **Transition arena:** long-term activities in which the future is jointly deliberated and envisioned.
- **Transition agenda:** activities aimed at the medium and long term, with a focus on changes in existing organisations, institutions, rules, and physical or financial infrastructures.
- **Transition experiments:** short-term activities that focus on experiments and actions that practice, test, and exhibit alternative ideas, practices, and social interactions.
- **Transition monitoring:** activities targeted at learning about the system's current state and dynamics, as well as probable future states and the path from present to future: These include continual operational, tactical, and strategic actions that provide (collective) learning.

In the literature, Cramer (2020a) has dealt with this issue by focusing on CE implementation built upon TM theory and processes that may indicate change orientation. The author advocates implementing CE initiatives as a continuous transformational change process to influence initiatives that speed up changes and can be scaled up towards a full CE in a local context. As the adoption of IS as an enabler of the CE has been slow and among many reasons the lack of strategy in the regions is one of them, it is relevant to unfold implementation activities. Industries are reasonably accountable for depleting resources, they play a pivotal role in societal transitions between the business environment and the wider environment to achieve a sustainable model (Bidmon & Knab, 2018). Case studies describing the creation of regional symbiotic networking strategies are among the gaps in the literature that should be filled. Consequently, studies that allow comparisons under the umbrella of the TM process to generalize outcomes are valuable (Cramer, 2020b).

3. Methods

The Humber Region in UK is studied through a qualitative case study using the conceptual TM framework **(**Figure 1**).** The conceptual framework was described and analysed through interviews and developed to generate action strategies to recommend implementing it.

Case study research

Transitions study, when viewed as processes of change with complicated chains of causation, multiple players, and changing framework conditions, arguably necessitates process-oriented approaches to analysis (Geels & Schot, 2010). Typically, how transition processes are analysed has been in the form of comparative meta-analyses, case studies, and surveys (Köhler et al., 2019). The substantial dependence on case-based approaches has more to do with the process than with outcome or indicator-oriented modes of theorising. Thus, for this study, the case study approach will be used as it reconstructs transition processes over decades, leading to a better knowledge and explanation of transition dynamics (Köhler et al., 2019). Case studies are a well-accepted method of inducing theory from qualitative material buried in practice (Yin, 2003). Case study research is frequently employed in novel areas and when aiming to explore and comprehend rather than quantify and confirm (Yin, 2009). Given the relative novelty and emergence of industries engaging in initiatives related to an IS within a CE, case studies are thought ideal for investigating this phenomenon.

The Humber region was selected for this study for the opportunity to learn about early actions done by one of the first UK IS initiative, the Humber Industrial Symbiosis Programme (HISP) which was first attempted to start in 2000. This effort sparked the adoption of similar programs in other parts of the UK (National Industrial Symbiosis Programme (NISP) as well as the completion of smaller projects in the Humber area (Cervo et al., 2020). Cases were created and analyzed using two different forms of data: documentation and interviews.

Document review: To gain knowledge of the Humber region's initiatives, documents such as sustainability agendas and environmental programs were analysed. A literature review was carried out to gather information about IS over the last 10 years. The first step involved a search in the scientific literature database Web of Science Core Collection (WOS), the most commonly used and robust source for literature review (Kamalski & Kirby, 2012) to carry out this analysis. WOS's Cited Reference Search tool was used as a starting point for selecting relevant publications. This step allowed it to generate a list of 1113 records that mentioned the keyword "industrial symbiosis". Likewise, the search was limited to peer-reviewed journal articles, review articles and book chapters (all published in English) as this is the dominant mechanism for quality control in conducting unbiased knowledge synthesis in most scientific disciplines (Bornmann, 2011). This step led to an output of 893 relevant publications.

Then, to select literature in the final sample, the publications were assessed to meet two criteria of eligibility (Gottinger, Ladu, & Quitzow, 2020): (i) the study addresses IS in the UK; (ii) the study deals with the Humber region. After excluding literature that did not meet the criteria, a full selection of 93 studies was selected. The studies in the sample were published between 2011 and 2021. The bottom-up change was also explored with the interviewees to build a more integrated vision of how the transition has emerged in the region.

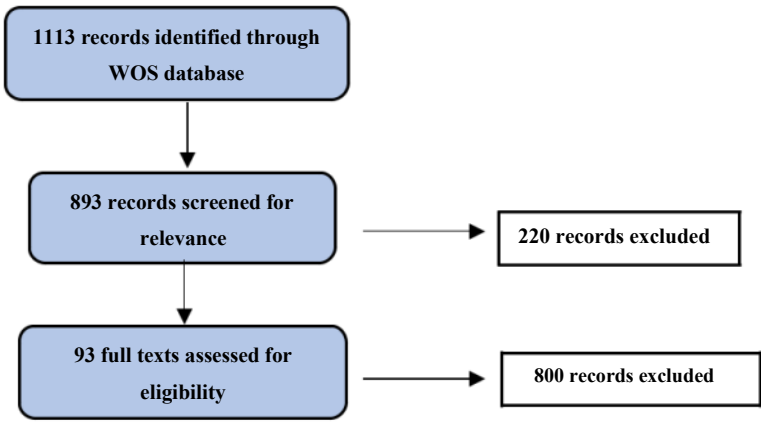

Figure 2 *Literature review process*

Semi-structured interviews: eight semi-structured interviews were performed with a different group of stakeholders (business, business association, local and regional administration and agencies, and research institutions) in the Humber region to gather insights into how different stakeholders have been working in the region ever since the HISP was initiated. At least one actor from the stakeholder's type (Table 1) involved in IS in the region was interviewed to provide insight into how the region approached IS as well as the initiatives that are currently occurring. This not only guarantees that the information gathered is similar but also allows an interviewer to pursue an intriguing line of questions (Kvale & Brinkmann, 2009). The purpose of this type of interview is to learn about interviewees' organisational experiences in a focused and detailed manner, revealing perspectives, feelings, intentions, and actions, as well as the context and organization of their activities, to better understand the reality within organisations (Saunders, Lewis, & Thornhill, 2009). Stakeholders were specifically questioned about efforts centred on by-products to promote resource efficiency and value creation from waste.

Table 1 *Overview interviewees*

Stakeholder type	Role	Organisation type
Business	Environmental manager	Chemical
	R&D manager	Manufacturing
	Company Manager	Services
	Director	Renewable energy
Business association	Program Manager and Energy Hub board member	Services
Local and regional administration and agencies	Climate Change Manager	Services
Research institutions	Researcher	Services
	Lecturer	Services

Data analysis

The interviews in this study were video-recorded and subsequently transcribed to assure the accuracy of the data. The interview transcripts were reviewed and classified separately. An explanation-building strategy, albeit iterative, was utilized as a deductively based analytical way to evaluate a theoretical notion (Yin, 2003). While gathering and analysing data, an attempt was made to construct an explanation by initially matching certain categories obtained from prior research and literature to develop a transition towards CE (de Souza et al., 2020).

The coding approach produced results that aided in comparing initial categories and iterating this process until a satisfying explanation for links between IS activities and stakeholders were obtained (Yin, 2003). The created codes were then analyzed using the MAXQDA software, which is widely used in qualitative research to investigate the relationships between multiple responses (Saunders et al., 2009), and in this study to seek new insights on how specific experiments and actions towards the CE can be deepened, broadened, or upscaled to a cleaner mode of production.

4. Results and Discussion

This section shows the results obtained in the Humber region. The observations obtained during the literature review phase were contrasted with the responses obtained in the interviews to generate new information that

would allow us to apply the concepts from the TM literature to develop a conceptual framework. And to describe the main characteristics that would allow the region to move towards an efficient resource management model through the analysis of the activities initially implemented and their relevance for the transition.

Transition arena

The first component is establishing a transition arena where goals and modes of collaboration with local stakeholders are developed. Based on information gathered from literature and interviews, the need to establish a governmental zero waste to landfill policy and the commitment to promote IS were key in establishing a common goal for this transition. One reason why the success of IS in its early days is attributed to the landfill tax, is because this forced companies to change their strategy from sending waste to increasingly expensive landfills. By doing so, the UK policy framework supported the establishment of IS networks by providing a necessity for businesses to enhance their environmental performance (Jiao & Boons, 2014). A private entity initiated the facilitation of industrial symbiosis to help companies reduce costs and risk, and open new business opportunities. They helped companies to find partners who could use their waste as raw materials to grow synergies between companies (Abreu Ceglia, 2018; Costa, Massard, & Agarwal, 2010). Eventually the UK government funded pilot initiatives including in the Humber region, before the National Industrial Symbiosis Programme (NISP) was established.

Factors such as institutional framework, governance arrangements, and solid commercial potential were deemed crucial (Abreu & Ceglia, 2018; Lombardi & Laybourn, 2012), and different programme attributes influenced the development of the IS programme in the Humber region (Table 2). Although many companies expressed interest, the sense of commitment to the program, as well as the degree of contact among them was initially low. In addition to limiting the opportunities for material networks, weak technological compatibilities within sectors were linked to organisational cultures with low degrees of experience with inter-firm cooperation, which has resulted in some reluctance to participate in the program in its origins (Mirata, 2004). This was the result of fragmented industrial development, and it depicted, a technical environment with limited opportunity for synergies to emerge within various sectors. Similarly, Humber facility managers' restricted decision-making powers were another factor holding back the program. So, agreements presented and facilitated by a consultant and voluntary participation in the program with no fees charged but paid for by the government in services such as opportunity identification improved NISP’s effectiveness (Jensen, 2016).

Table 2 *Characteristics of the IS in the Humber region (Mirata, 2004)*

	Industry structure	Position of coordinating body	Project championship	Original institutional and framework	Awareness raising and commitment
Humber region	Difficult to integrate due to technicalities	No clear coordination	No industry-led frontrunners	Low level of cooperation	Fragmented

Likewise, IS network development and operational characteristics were influenced by several interrelated elements. The coordination tended to place too much emphasis on initiatives, which was incompatible with the important and valuable intention of engaging industries from various sectors in the program. The most prevalent tasks of coordination were mostly assisting with informational and organisational concerns, as well as obtaining various types of support for the programs, including financial support. A few crucial aspects and their possible impact on IS networks are summarised in 5 categories: 1) technical, 2) political, 3) economic and financial, 4) informational and 5) organizational and motivational. So, the Humber area has established great knowledge in waste-to-resource technologies as a result of its involvement in initiatives to promote IS for over a decade (Jensen, Basson, Hellawell, & Leach, 2012; Mirata, 2004; Velenturf, A 2016). Facilitating such synergies between companies played a key role for as long as the funding has lasted. Since 2012, public organisations and local administrations involved in the development of IS in the Humber region have either lost public financing – most notably NISP itself – or has been dissolved or faced substantial funding cuts (Velenturf, A. 2016). As a consequence, the feasibility of maintaining a collaborative culture based on these processes and the role public actors could play in IS projects outside entities like NISP became more of a hurdle.

The UK government withdrew from the NISP initiative, expecting it to be mostly driven by the private sector. It was thought that because NISP was so successful, companies would start paying for the service. Alternatively, established actors such as waste managers could facilitate industrial symbiosis. However, in the more than 10 years since the programme stopped receiving public funding, private actors have generally not facilitated new symbioses between companies. The fact that it was government-funded alleviated some of the inherent skepticism that businesses had about working together since they recognised that it was overseen by an impartial authority.

The challenge for companies has been to find commercial viability to the symbiosis model as the waste exchange was free for customers and recipients, which helped drive the IS model. A problem faced by businesses and local authorities is that much of the waste is not being monitored as there is no obligation to

do so, which prevents symbiosis based on an understanding of the industrial diversity of the area and its materials to determine the possibilities for symbiosis. Although there have been cases where companies have continued to promote IS and have made it a strategic element in their business model. Markets such as biodiesel production developed through NISP have seen an opportunity and have grown because of this.

So far, nothing has come forward to fill the void when the government money runs out. This, according to interviewees, proposes a new vision of IS in which the context should be based on the diversity of materials over any geographical distance. Given externalities such as Brexit and Covid-19, local authorities see IS as a cost-effective way forward. Currently, authorities are once more interested in facilitating IS as they see it as an opportunity to accelerate a regenerative economy that supports local economies. Nevertheless, interviewees argue that there is a need for staff on the ground to talk to businesses and connect with different points in the value chain to realise symbiosis. Another problem that has been highlighted in the interviews has been the slow pace at which environmental regulations are not evolving at the same pace as technological innovations.

Moreover, the industrial landscape has changed and many elements that were successful in the past may not be successful if they were to be implemented again as the industrial ecosystem evolves according to the interviewees. Yet, the companies consulted agree that the future of sustainable industries will only move forward if they make business sense and are supported in their early stages by government intervention through incentives such as public procurement or subsidies, otherwise, their momentum in a 2.0 program is unlikely. But, due to the lack of continuity in the programme, expert knowledge will be less because of the retirement of the people involved in the development and evolution of the program. Though, it has been mentioned that social innovations must be part of the model to gain social acceptance from different parties and that they must have greater consumer involvement to push for more sustainable modes of production.

At this early stage of the transition, it appears that the very elements that brought the creation of symbiosis to life are the elements that are impeding a long-term vision of transition (**Figure** 3). A commitment sustained solely by a commercial objective has meant that a lack of support and continuity of public policy, especially funding, can be seen as the elements that have not allowed the initial vision to continue in this part of the transition. This is reflected in the fact that only two types of stakeholders are defined: a) those who finance initiatives that facilitate the symbiosis and generate the regulatory framework, represented by local and national governments, and b) the stakeholders who receive the money to carry out the implementation of the IS programmes, represented by companies and business associations. Other authors such as Rincón-Moreno et al., (2021) and Hein et al., (2017) have highlighted the same problem and the need to include another group of stakeholders that collaborate in the achievement of the IS. In that sense, authors such as Ghinoi et al., (2020) have created a wider group of stakeholders that can help consolidate the transition and support the already established roles of companies and governments. Stakeholders who play a less economically driven role could

serve as trusted third parties as coordinating functions must be maintained to achieve the required continuous increase in network performance. However, the commercial viability of the projects should be considered relevant.

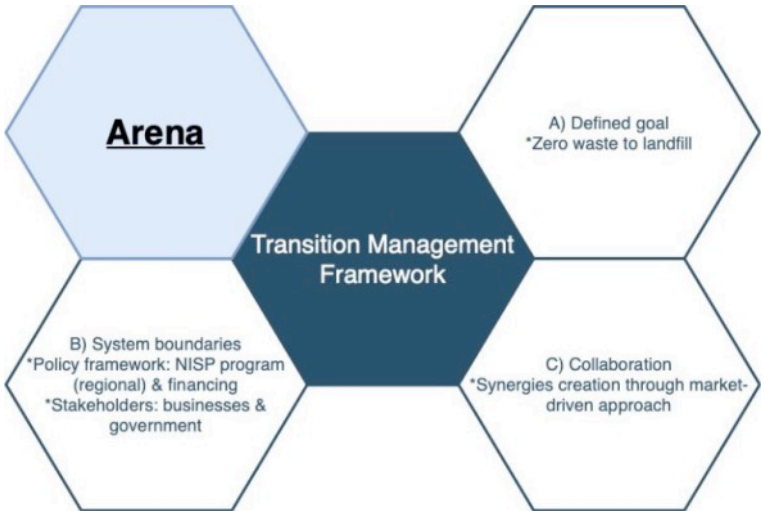

Figure 3 *Transition Arena analysis*

Transition agenda

The second component of the TM framework is called Agenda. The agenda is built on a shared awareness of the problem's persistence, the need for a transition or drastic change, and a set of guiding principles for the envisioned transition. The emphasis here is on linking the long- and short-term, as well as anchoring new visionary visions in agendas, programs, and potential regulations. Furthermore, the transition agenda is reflected in changes to institutional structures and framework circumstances, such as new governance structures that promote cooperation and self-organization, new alliances, or new finance possibilities. The agenda has a special function in TM by serving as a "compass" for the "search and learning process" that lies ahead (**Figure** 4). Throughout the innovation process, government agencies play a significant role (Frantzeskaki, 2022; Kumar, 2021; Peterson, Baker, Aggarwal, Boyer, & Chan, 2022).

Building on the industries present in the region, this “compass” involves energy supply, manufacturing, and agriculture activities and carries out waste-to-resource exchanges in a network that provides bio-based developments in the energy sector and optimises material and energy flows, including waste The public and private drive to implement waste-to-resource innovations in the bioenergy industry made the Humber region ideal to contribute to innovation progress towards IS between agriculture, waste aggregators, biodiesel

production, and construction, all of which have a wide range of inputs and outputs, were determined to be extremely central, along with the port, a critical link in supply chains, and industries that cycle materials from waste product to resource (Penn et al., 2014).

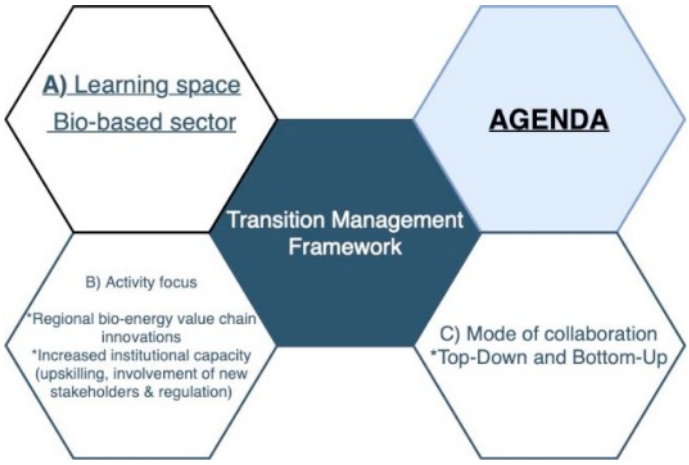

Figure 4 *Transition Agenda Analysis*

However, since 2012, the governance network in the Humber region has diminished due to funding cuts in a context wherein a lack of strong policies on environmental regulation and climate change adaptation weakened the governance capability to play an active part in the regional network. Currently, the regional governance system has a limited capacity to participate in planned collaborations and operationalise national government objectives and plans. Nowadays, local entities are trying to re-enforce IS through the CE strategy proposed for the region. The role of regional government in terms of planning and environmental licenses, as well as luring investment, appears to be underscored (Velenturf, A. 2016).

Some local authorities believe that their role should be more associated with building capacity to support companies to seek opportunities among themselves. Flexible progressive participatory frameworks in which companies and regulatory agencies co-produce plans for the implementation of regulatory objectives have been used in for example the water sector (Breman, Pleijte, Ouboter, & Buijs, 2008) and could also be used for waste-to-resource developments. Velenturf, A.(2016) suggests that regional governance actors should devote resources to attracting expert knowledge on both technical and social aspects of biowaste-to-resource innovation, as well as training regional governance officers in emerging technologies, to increase regional capacity.

This increase in institutional capacity has been referred to by interviewees as an additional issue to the financing of IS initiatives, making them crucial actors through strong government policies that comply with the execution of value-creating IS and promote collaboration through intermediary stakeholders.

However, stakeholders such as the research institutions (RI) consider that there is a need to obtain facilitation services, for small and medium-sized enterprises to amplify the benefits of adopting a IS through innovative waste solutions. It has also been argued by the interviewees that it is the existing stakeholders in symbiotic relationships that should secure funding through local enterprise partnerships because they can access regional development funds supported by local consultancy services that bridge the gap between companies. According to interviewees, the role of the facilitator or a trusted partner who should be a third party is mentioned as a crucial component in the development of IS by seeking to bring together and target companies with similar waste streams to achieve synergies aided by established digital solutions and a waste database. It has also been mentioned that this role should be composed of local people who build trusting relationships between the parties. One of the roles that this new stakeholder should play is to know in real time the volumes, quality, and reliability of waste collection to build confidence in the supply chain.

Unfortunately, this role is not defined as it has not been funded by the government for the last 10 years. Although it has been stated in the literature that enterprises in an IS can self-organise, as has been the case in the Humber region, as one of the ways in which symbiotic relationships can be developed (Yazan, Romano, Albino, Fraccascia, & Giannoccaro, 2016), in the ca. 10 years without government support, these symbioses have generally not materialised. To overcome this problem, Velenturf (2016) mentions that governance in the Humber region should be focused on: a) improving regulatory 'landscape' integration and flexibility across government departments; b) improving connections between national and regional government organisations, as well as within the Humber region; and c) investing in regional governance actors' knowledge, skills, and operational capacity.

On a similar note, Velenturf (2017) argued that actors who serve as network brokers for industrial symbiosis should be better understood due to their commercial interests in resource synergies. Incentives have played an important role but clearly IS has been lagging without a facilitator to link top-down policy targets with bottom-up processes. (Velenturf, A. 2016). Regarding transition theory, transition brokers can improve regional change processes, build alliances, help generate the required preconditions, and launch meaningful circular projects as an intermediary, impartial players without being regarded as working in their self-interest. They function as a conduit between businesses and other necessary parties to help prepare, negotiate, and seal a circular contract, as well as scale up and mainstream these activities (Cramer, 2020c).

Transition experiments

Transition experiments refer to day-to-day activities such as innovative experiments in which spaces for experimentation and collaboration can be created, how and which actor networks can be mobilized, and what action policies and strategies can be recommended to bring about change (Kumar, 2021; Peterson et al., 2021).

An experiment is a multi-actor approach, which means that the local government is also one of the participants. Transition experiments provide new avenues for proactive engagement with actor role shifts, both deliberate and unintended (Dóci et al., 2022).

As mentioned in the previous sections, funding for NISP has stopped and no government initiatives on symbiosis have been promoted for approximately 10 years in England. However, some initiatives continued because a) there was a clear commercial incentive to pursue them and b) there were defined collaboration roles among the various stakeholders that made symbiosis possible. Table 3 recaps the types of experiments developed by the different stakeholders and those in which they have been indirectly involved. The following list of experiments (Table 3) is not intended to be an exhaustive list of all the IS projects underway in the Humber region, but as many of the interviewees are still closely linked to the original program either directly or indirectly, their responses reveal a snapshot of what the transition has been and what it could become.

Companies and government entities stand out as the type of stakeholders that have led the highest percentage of transition experiments (90.32%) in the region. The experiments that have been promoted most by the companies have been related to partnerships in the chemical and manufacturing sectors such as cooperation to carry out projects or to establish a cooperation framework that allows synergies to be implemented. Also, pilot projects in sectors such as bioenergy that serve as examples to be scalable or demonstration projects in the glass industry that can be useful in the cement industry are among the symbiosis projects that are in the works.

Table 3 *Transition experiments in the Humber region*

		Chemical	Industry-wide	Manufacturing	Renewable Energy	Services
Businesses	Innovation project	1.6%			1.6%	
	Landfill diversion					1.6%
	Methodology					1.6%
	Partnerships	3.2%		6.5%	1.6%	
	Pilot project		1.6%	3.2%		3.2%
	Procurement			1.6%		

	Remanufacturing project			1.6%		
	Reports					1.6%
	Research project			8.1%		1.6%
	Technological innovation	1.6%			3.2%	
	Training					1.6%
	Waste characterisation			1.6%	1.6%	1.6%
	Waste market	1.6%		3.2%		
	Waste recovery project	3.2%	3.2%		1.6%	
	Workshops					1.6%
Business associations	Grants		1.6%			
Local administration	Economic incentive scheme	1.6%				
	Grants		1.6%			3.2%
	Partnerships		1.6%			4.8%
	Procurement		1.6%			
	Reports		1.6%			
	Research project			1.6%		
	Training		3.2%			
	Waste recovery project					1.6%
	Workshops		1.6%			
Research institutions	Partnerships		1.6%			
	Pilot project		1.6%			
	Technological innovation		1.6%			
	Waste characterisation		1.6%			
	Waste market		1.6%			

Other types of experiments that have been mentioned are research projects, mostly carried out by universities or consortia of research centres. Typically, these types of experiments seek to find potential uses for certain

materials that can be recirculated within the business fabric. Typically, the experiments were developed on a laboratory scale to test the feasibility of these wastes having a better use than being sent to the landfill, without yet considering whether they have any commercial applicability. On the other hand, the experiments that refer to waste recovery projects allude to materials that already have sufficient volume to have commercial scalability. Thus, using the methods already established in companies, new alternatives are emerging for waste management such as obtaining biofuels from food waste or obtaining 'green chemicals' in the lime industry.

On top of that, the experiments carried out by governmental entities are related to partnerships, which makes sense given their role of being a key participant in the transition. This type of experiment is focused on achieving regional economic development through this type of governmental strategy and as a stakeholder that guarantees collaboration between companies. Thus, it is also understandable that if governments are involved in partnership issues, they will be involved in experiments such as grants, since one of its main roles is the money, it invests in different initiatives aimed at impacting the greatest number of organisations to create synergies.

Similarly, experiments such as training through support programs for companies and increasing the capabilities and skills of the workforce in industries such as the turbine blade manufacturing plant in Hull stand out. The experiments shown here demonstrate how local governments and businesses have been the major promoters of experiments. As the objective of any transition is to bring together those stakeholders who can enable the transition, having only two major stakeholder groups would suggest that they are not yet mobilising the necessary actors for this stage to bring about change.

Therefore, to understand how the experiments are being mobilised among the different stakeholders, a comparison of the experiments carried out with and without cooperation across actor types is made. Table 4 shows that research institutions have the highest percentage of cooperation with companies. As shown in Table 3, these types of experiments are more related to research projects with possible industrial application. Likewise, business associations collaborate exclusively with local governmental agents. This is explained by the reason for the existence of the business associations, which serve as a bridge to funnel local funds to businesses.

Table 4 *Collaboration between stakeholders*

	Businesses	Business associations	Local administration	Research institutions	No cooperation
Businesses	34%	10%	5%	15%	37%

Business associations	0%	0%	100%	0%	0%
Local administration	40%	27%	13%	7%	13%
Research institutions	80%	0%	0%	20%	0%

Likewise, 34% of businesses collaborate with other businesses, while 37% of the experiments in IS are conducted without any cooperation between different type of actors. As could be expected in the absence of an overarching facilitator, the experiments currently being conducted in the Humber region are fragmented and without much multi-stakeholder traction. Transition experiments (**Figure** 5) identify areas for experimentation and cooperation, how and which actor networks can be mobilised, and what initiative policies and strategies can be recommended to effect change (Frantzeskaki, Hölscher, Bach, & Avelino, 2018). As an iterative process that can be executed in parallel, the TM framework could suggest that from the transition of arenas, the goals set for the region could be rethought to create a transition with a broader multi-stakeholder group that would allow for joint goals to be set. It is a simple but effective activity that can be used as a jumping off point for learning and to demonstrate a visible action that is accessible, encourages debates and discussions that change people's thoughts and perceptions, and can be adopted and owned by the community (Peterson et al., 2021). This in turn would result in experiments that show a higher percentage of collaboration between the different stakeholders and would ensure a more effective transition.

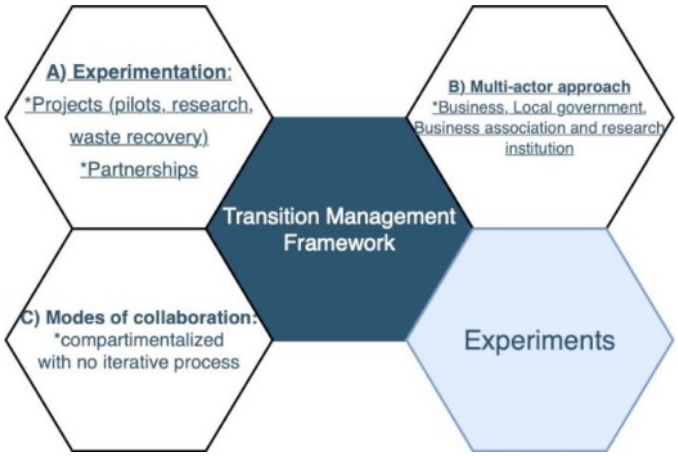

Figure 5 *Transition experiment analysis*

Transition monitoring

Monitoring is an important aspect of the transition process. This level should not be segregated from the others (arenas, agenda, experiments) because it is an intrinsic part of governance processes and should feed into activities at the other three levels (Wittmayer, Steenbergen, Frantzeskaki, & Bach, 2018). Monitoring, assessing and learning from the transition experiments, as well as revising the vision, agenda, and coalitions, are all part of this phase (Frantzeskaki, 2022). It also assists actors in continually adjusting their aims and behaviours by understanding and accounting for changes at all levels. Short- and long-term monitoring and evaluation are crucial in the last step of this iterative cycle to measure the effectiveness of the transition process, which then feeds back into further adoption and development, influencing the larger landscape dimension (Kumar, 2021). Adaptations can be made in the desired direction of the system, in different experiments, or the transition agenda based on monitoring insights (Peterson et al., 2021).

Table 5 *Suggested monitoring indicators by interviewees*

Stakeholders	Sector	Monitoring
Businesses	Services	Tonnage moved of waste
Business associations	Services	Carbon emissions Waste diverted from landfill
Local administration	Industry-wide	Number of new products designed

In this part of the analysis of the transition in the Humber region, monitoring and evaluating are based on the lessons learned from the experiments, followed by any necessary adjustments to the vision or agenda (Dóci et al., 2022). Therefore, once funding for the program stopped, there was no further evaluation of previous processes or experiments that would allow changes to be made to the agenda or arena.

However, in this study, stakeholders have been asked about the monitoring indicators (Table 5) that they propose or have used to evaluate the progress of the experiments. Monitoring indicators suggested or used by stakeholders such as LCA or carbon emissions tracking could be used in a cross-cutting manner if they were to become part of the transition evaluation. As there is a disconnect between the experiments and the rest of the stages of the transition as they were not conceived from the beginning, adjustments to the agenda and vision do not seem to have been impacted (**Figure** 6).

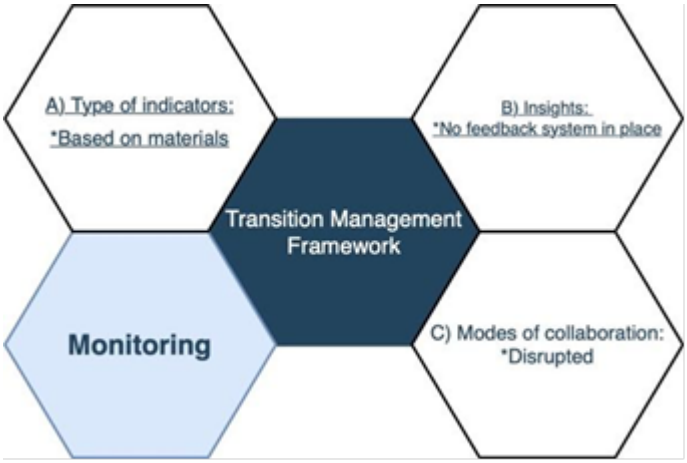

Figure 6 *Transition monitoring analysis*

5. Conclusions

This study has aimed to integrate and use concepts and learning from the emerging area of TM to systematically investigate how to move from a linear system to a more sustainable mode of production. The concepts of the TM framework have been applied to analyse IS in the Humber region. The four cycles of the TM framework have been used to analyse the emergence, decline, and re-emergence processes that have taken place in the region. It could be argued that under the lens of the transition arenas, goals, boundaries, and collaborations were crucial for its initial success. But issues such as more funding and the commitment of more stakeholders to participate in the visioning process could help strengthen the transition.

Key to the process could be the integration of more stakeholders that fulfil the role of brokers, with a less commercial profile and a more social nature that engages more actors and offers trusting and long-lasting relationships. In the last parts of the framework (Experiments and Monitoring) there have been many projects in a symbiosis that have sometimes been consolidated but have not been evaluated to generate and/or evidence substantial changes towards a transition.

As can be seen, the IS programme in the region was a success as long as funding lasted for an independent third-party facilitator, and for government agents to have capacity to collaborate on these initiatives. The activities initially implemented are still relevant if a transition using the TM framework were to be considered. The opportunities offered by an iterative process such as the TM framework would lead to a more solid foundation in the region to ensure and accelerate the transition to a cleaner and more efficient industrial system. It is expected that these findings might subsequently be extended to other locations to improve industries in developed economies, and to help prevent emerging economies from becoming entrenched in unsustainable management as industrial outputs increase.

Acknowledgement

The authors would like to thank the University of Leeds and TransFIRe: The Transforming the Foundation Industries Research and Innovation hub (TransFIRe (EP/V054627/1) funded by UKRI. This research was also funded by the Provincial Council of Gipuzkoa. We would also like to thank the interviewees for dedicating their time to speak with us.

Abstract

Buildings consume an enormous amount of primary energy and are responsible for a large share of greenhouse gas (GHG) emissions, causing global warming and climate change. In order to limit their negative environmental impacts, concerted efforts have been made to cut off GHGs emissions, especially CO_2. Nonetheless, to date, most discussions and solutions are focused on the building's operation phase, whilst construction materials may account for up to half of the overall CO_2 footprint of new buildings. Additionally, the buildings and construction industry consume approximately half of the natural resources extracted for materials worldwide, putting significant pressure on global resources. These have highlighted the need to reduce the negative impacts of materials used in buildings. Recent studies suggest that circular bio-based materials (C3BMs) may represent a coherent solution. Indeed, C3BMs can be defined as "materials resulting from by-products and biowaste of plant or animal biomass that may be utilized as a raw material in construction and decorating items, as well as building materials". Hence, their utilization can improve the environmental performance of buildings (e.g., reducing embodied GHGs emissions, sequestering CO_2 emissions, etc.) and may bring social and economic benefits. There are many studies on using bio-based materials to develop building components or install them into buildings. Nonetheless, these studies are still fragmented due to the difference in types of material and their biological origin, research objectives, and methods employed to assess the sustainability of the case studies. Therefore, the need for systematic categorization is more than evident to equip stakeholders in the building sector with a comprehensive picture of this emerging approach. In this context, the present study aims to fill the gap by undertaking a systematic and bibliometric literature review of relevant studies. The paper categorizes case studies in the extant literature into different levels and reviews methods used to evaluate their sustainability. For this to be achieved, the analysis uses research questions to guide the process, searches guidelines for choosing

case studies to analyze, and assesses identifying criteria for determining what information to extract. The reference sample of scientific papers is extracted from online databases, including Web of Science and Scopus, and analyzed using Microsoft Excel, VOSviewer, and Biblioshiny R application. This study reports the preliminary outcomes of the literature review conducted. A more detailed systematic analysis will be developed beyond this paper for future publications.

Keywords: Circular bio-based building material (C3BM), Sustainability, Circular economy, Sustainability assessment method, Building sector.

1. Introduction

Buildings account for almost 35% of worldwide energy consumption, 55% of total global electricity use, 25-30% of solid waste, and 38% of global CO_2 emissions (United Nations Environment Programme, 2020). Hence, a recent report of the Intergovernmental Panel on Climate Change has stated that "*1.5 °C-consistent pathways require building [GHG] emissions to be reduced by 80–90% by 2050"* (Heleen de Coninck et al., 2018). In addition, the built environment places enormous strain on global resources. Indeed, the construction industry (CI) greatly depends on virgin materials (United Nations Environment Programme, 2020). Only buildings and infrastructure, especially in developing nations, consume between 40% to 50% of resources extracted for global materials (Marc de Wit et al., 2018). Plus, with the need for new housing and infrastructure to meet the requirement of population and economic growth, the construction materials demand is expected to continue increasing. By 2060, the materials consumption globally is forecasted to be more than double, and the materials consumed by the CI will comprise a third of this rise (United Nations Environment Programme, 2020). Moreover, approximately 15% of materials in the CI are wasted annually, and this figure is still rising (United Nations Environment Programme, 2020). These facts may cause the depletion of nonrenewable natural resources and a wide range of environmental impacts globally (United Nations Environment Programme, 2020).

Targeting to lower the non-renewable material and GHGs emissions footprint of the CI, different initiatives have been proposed. Among them, transforming the built environment from linear to circular economy (CE) models, and applying a bio-economy (BE) model in the sector, are determinant strategies (United Nations Environment Programme, 2020). Many definitions of CE exist, and its precise meaning and scope remain the subject of debate (Cecchin et al., 2021). However, CE can be defined as "*a regenerative system in which resource input and waste, emission, and energy leakage are minimized by slowing, closing, and narrowing material and energy loops"* (Geissdoerfer et al., 2017). Meanwhile, BE is defined as the *"production of renewable biological resources and the conversion of these resources and waste streams into value added products, such as food, feed, bio-based products and bioenergy"* (European Commission, 2012). The former, in the CI, can boost the material efficiency strategies,

which might help to cut total life cycle emissions from buildings and construction works, especially residential ones, by up to 35-40% in Group of Seven (G7) countries (IRP, 2020), for instance. Likewise, the latter provides opportunities to substitute conventional materials with renewable and lower GHGs emissions materials (Carus and Dammer, 2018).

It is noted that CE and BE are two different yet complementary approaches, and their intersection is defined as a "circular bio-based economy" (CBE) (Carus and Dammer, 2018). Other scholars argue that the CBE is a CE where *"nonrenewable […] inputs to industrial systems are replaced by renewable biological resources"* (Temmes and Peck, 2020), or the application of the CE concept to biological resources, products, and materials (European Commission, 2017). Thus, the utilization of Circular bio-based building materials (C3BMs) within the CI can help to combat climate change and the other environmental impacts in the sector. Indeed, this solution may help reduce the amount of waste in landfills (Rabbat et al., 2022) and can bring opportunities to convert C3BMs into heat, energy, alternative fuels, and materials at their end-of-life (EoL), which can create considerable revenue. This alternative is anticipated to reduce thousands of tons of CO_2 emissions and save a tremendous quantity of fossil fuels (Rabbat et al., 2022). However, using these materials may cause critical issues if lacking a comprehensive approach to properly dealing with their EoL (Rabbat et al., 2022).

It should be highlighted that no specific definition for C3BMs or even "circular bio-based material" (C2BM) could be found in the literature. Nonetheless, C2BMs can be understood as bio-based materials that fit the context of CBE. The bio-based materials are defined as "*materials wholly or partly derived from materials of biological origin*" (European Committee for Standardization, 2014), while the CBE context refers to the potential reusing in cascading and organic recycling of by-products and biowaste of the biomass flow (Carus and Dammer, 2018). Hence, within the CI, C3BMs could be defined as "*materials resulting from by-products and biowaste of plant or animal biomass that may be utilized as a raw material in construction and decorating items, as well as building materials*". This definition is in line with the research done by Silva et al. (2021). Indeed, although the authors have not proposed a definition, they stated that particleboard made from waste is one kind of C3BMs (Silva et al., 2021).

According to the above definition, many kinds of C3BMs have been developed and presented in the literature. Notably, they are very heterogeneous in size, composition, shape, function, and biological origin. Nevertheless, they can be classified into three major groups: i) circular bio-based insulation materials (C2BIMs), ii) new concrete or binder and filler for concrete used for structural purposes, and
materials for indoor applications (e.g., ceiling, flooring, and furniture). It is found that C2BIM is the largest group, which encompasses a variety of types, such as particleboards (Silva et al., 2021), agro-concrete blocks (Azunna et al., 2019), etc. The dominance of this group is understandable due to C3BMs typically exhibiting comparatively low mechanical strengths. Consequently, they cannot be commonly employed as a material to form load-bearing members of a building (Amziane and Sonebi, 2016). The second largest group is C3BMs utilized for indoor

applications, mainly shaped as boards and composites like bio-flexi HDF fibreboards (Horn et al., 2018), and woody-like composites (Platnieks et al., 2020), etc. The last group includes concrete that uses fine aggregate, additive, or cement replacement originates from agricultural residue like rice husk ash (Gastaldini et al., 2014).

Noticeably, the last group is rarely mentioned as bio-based materials in the previous studies because the quantity of biologically derived materials is not significant in their total composition. However, they are partly derived from agricultural by-products, and their contribution to dealing with environmental crises related to the CI is vital (He et al., 2017; Hossain et al., 2018). Thus, they are referred to as C3BMs in the present study.

Existing studies of bio-based building materials, most of which are focused on the production and performance testing of these productions (Rabbat et al.,2022). For instance, (Maraveas, 2020) review the production of construction materials using agricultural wastes, while (Tlaiji et al., 2022) brief thermal and mechanical behavior of straw-based construction. Others focus on the development of binders for bio-based building materials (Bumanis et al., 2020) or fire-resistant biocomposites (Madyaratri et al., 2022), etc. Regarding the assessment methods, only a few articles have reviewed the methods used, mostly life cycle assessment (LCA), to assess the environmental impact of C3BMs. For instance, (Amziane and Sonebi, 2016) brief on the application of LCA for hempcrete, whereas (Miller et al., 2019) focus on concrete using rice-based ash and point out the limitation of studies on LCA and sustainability assessment for this type of material, etc. However, none of these studies reviews the methods to evaluate other sustainable dimensions, the sustainability or the circularity of circular bio-based solutions (C2BSs) in the CI in general and buildings in particular.

To the best of found knowledge of the authors, the present study is the first research that proposes a specific definition for C3BM and reviews case studies and methods to assess the sustainability of C2BSs at different levels in the building sector. To achieve these goals, this study uses a systematic and bibliometric literature review analysis of relevant studies. First, a definition for C3BM is proposed according to the existing definition of bio-based material and CBE. Afterward, the study categorizes case studies into different levels, then reviews assessment methods applied on each level. The study aims to provide a deeper insight into the current state-of-the-art research topic and the necessary bases for future studies and practices in assessing the sustainability of C2BSs in the building sector.

2. Methodology

A review of current scientific papers was conducted to analyze bibliometrics, the usage, and methods to assess the sustainability of C2BSs at different levels of case studies. The study adheres to a structured protocol to accomplish consistency, robustness, and transparency in the research. Indeed, the present review was carried out based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines (PRISMA) (Page et al., 2021).

2.1. Search strategies

A thorough literature review was conducted utilizing research databases to discover relevant scientific publications and papers. Several keyword combination searches were conducted to obtain relevant published papers from Web of Science (WoS) and Scopus (SP) - two of the most reputable and respectable research databases. Because the term C3BM has not been mentioned in the previous works, the search keywords in this study were defined based on the proposed definition for C3BM. Particularly, the search terms: *("building material*" OR "construction material*") AND ("food waste" OR "agr* waste" OR "food residues" OR "agr* residues" OR "forestry residues" OR "agr* by$product" OR bio$based)* was utilized to find the relevant literature.

The searches were restricted to the title, abstracts, and using the Boolean connectors "OR" and "AND" in search fields labeled "Topic" for WoS and "Title-Abstract-Keywords" for SP. There were no filters used in this phase to avoid database, publication, or language bias. Plus, to explore the big picture of the research topic, the keywords "case studies" and "assessment methods" were not included in the search query because they may not appear in the previous studies' titles, abstracts, and keywords.

2.2. Sample realization

The searches were conducted on February 5, 2022. Initially, the implementation of the described search strategies brought in 814 publications on SP and 381 on WoS, respectively. This resulted in a total of 1,195 papers, comprising all sorts of publications, such as research articles, reviews, editorials, book chapters, and others, being taken into account. The related literature data then was exported to the reference management program Endnote, identifying 78 duplicates.

The remaining 1,117 records were screened to only those written in the English language and published in peer-reviewed journals, allowing to eliminate 21 articles written in other languages and 293 conference proceedings, conference papers, book chapters, or grey literature. Hence, the 803 remaining articles were being evaluated for further screening.

Reading the abstracts of these papers allows for eliminating articles that are non-coherent with the search strategies. Particularly, the study did not consider papers that are not relevant to C3BMs or focus only on their development and performance testing. Consequently, 702 publications were excluded, and the remaining 101 articles were checked through the eligibility criteria. The criteria applied are "the authors assessed the sustainable dimensions, the sustainability or the circularity of C2BSs at different levels (e.g., materials, components, buildings, and building stock)". Because three papers could not be accessible, the full text of 98 articles was downloaded and checked, allowing to exclude 47 articles that did not fulfill eligibility criteria. Figure 1 displays the PRISMA framework implementation in the present review.

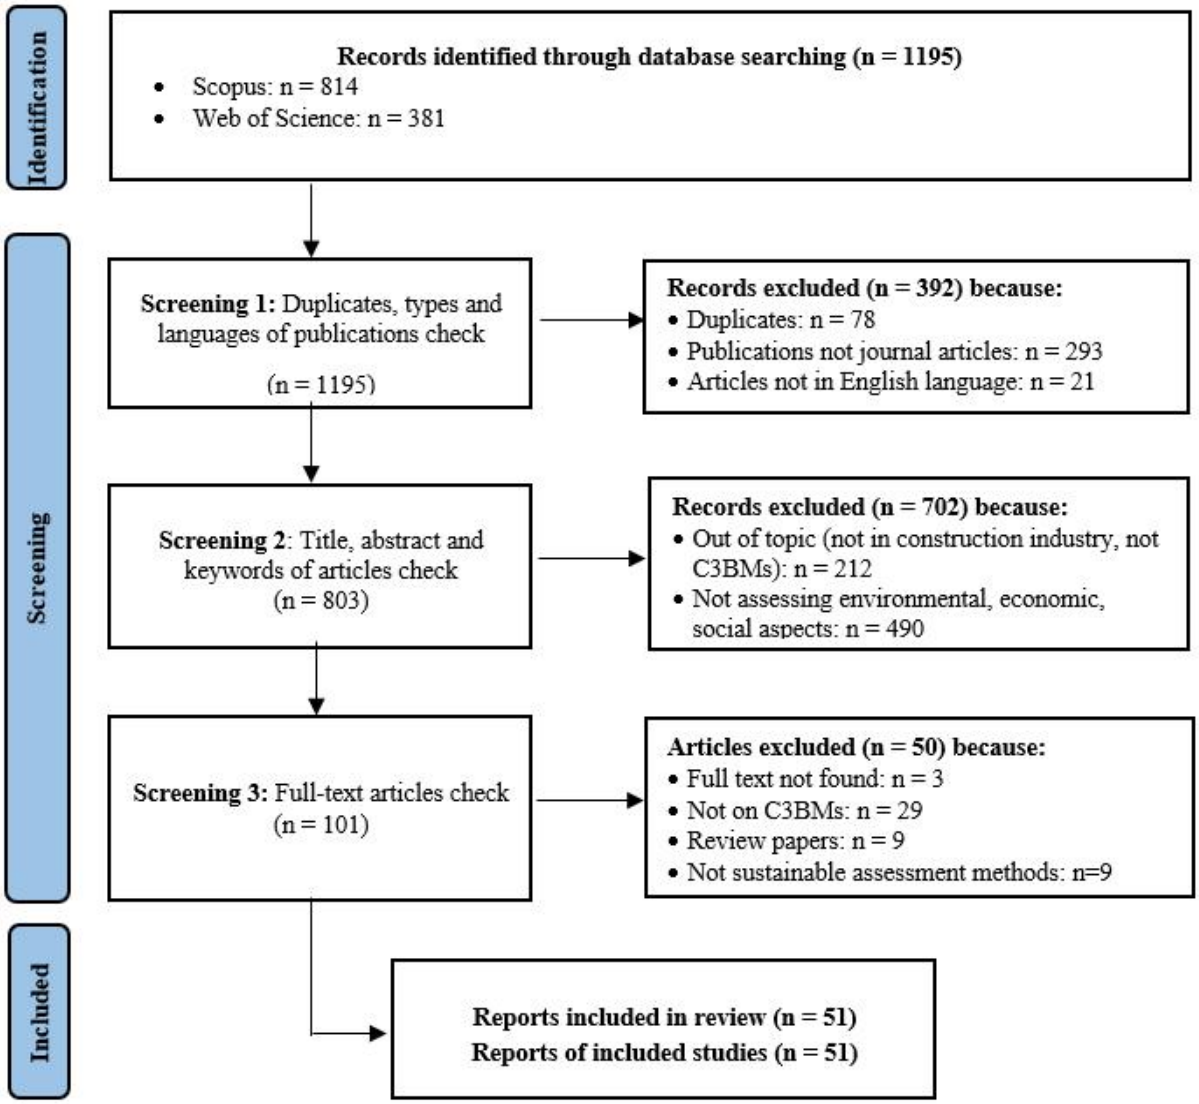

***Figure 1**. Sample selection framework (based on PRISMA guidelines).*

3. Descriptive analysis

This research is not focusing on the specific time frame for the papers. The year-wise distribution of publications' primary purpose is to understand the number of articles in a year selected and fulfill the review criteria. Figure 2 depicts the year-base graph of literature.

The oldest research paper found was published in 2014 (Pretot et al., 2014), and the number of records has risen dramatically yearly since 2018. Indeed, the figure for 2018 is nearly triple that of 2016 or 2017. The year 2021 contributed the highest number with fifteen articles, followed by 2020 with twelve documents. The graph also displays that more than half of the sample has been published in the last two years (2020–2021).

Noteciblely, the figure for only the first two months of 2022 (January and February) equals the whole year 2016 or 2017 and triple that of 2015. These reflect a very rapid increase recently in interest in the research topic.

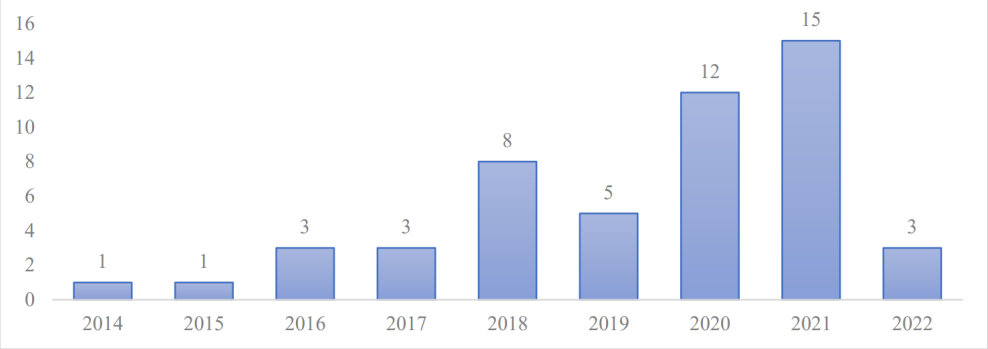

***Figure 2**. Distribution of literature year base articles.*

The journal-based publication analysis is carried out for the current study and realizes that the research works of the inventoried sample have been published in various journals. Indeed, 51 papers are distributed to 26 different journals. The "Journal of Cleaner Production" and "Construction and Building Materials" journals contribute the highest publications. The former accounts for about 19.6% (10), while the latter contributes 13.7% (7) of the inventoried sample. These are followed by the "Sustainability (Switzerland)" journal with the contribution of six papers, accounting for 11.8%. The two journals "Building and Environment" and "Resources, Conservation and Recycling" contribute equally to the sample, with four articles in total. The remaining journals altogether account for 47.1%.

Figure 3 presents the results of the research paper selected from each journal.

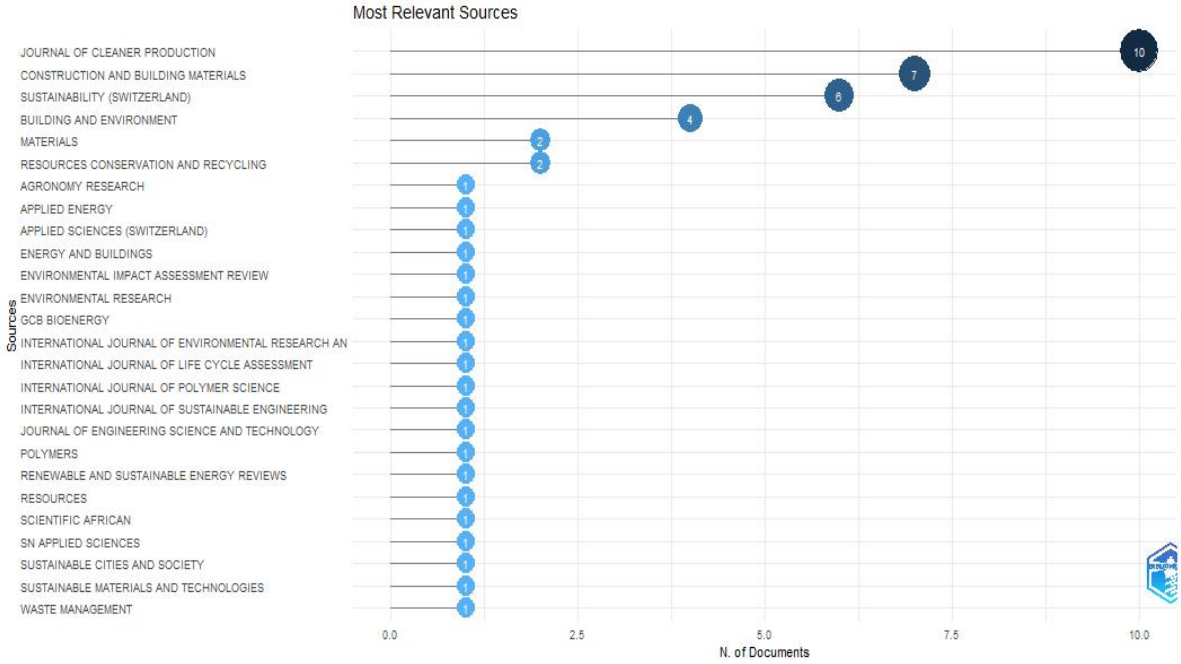

***Figure 3**. Contribution of literature journal-based articles.*

The co-occurrence network map is elaborated using VOSviewer (Cobo et al., 2012) and shown in Figure

The map depicts correlations among the leading author keywords used in the sample. Plus, the thickness of the lines indicates the strength of the correlations between the nodes, i.e., keywords, calculated by counting the number of articles in which the two keywords occur together (Gulotta et al., 2022). The test is performed only on the author's keywords reworked to harmonize the topics. The network clearly demonstrates connections among the keywords investigated. In particular, the map illustrates the centrality of the keywords "life cycle assessment", highlighting that most of the collected studies use the LCA approach to evaluate the performance of C2BSs.

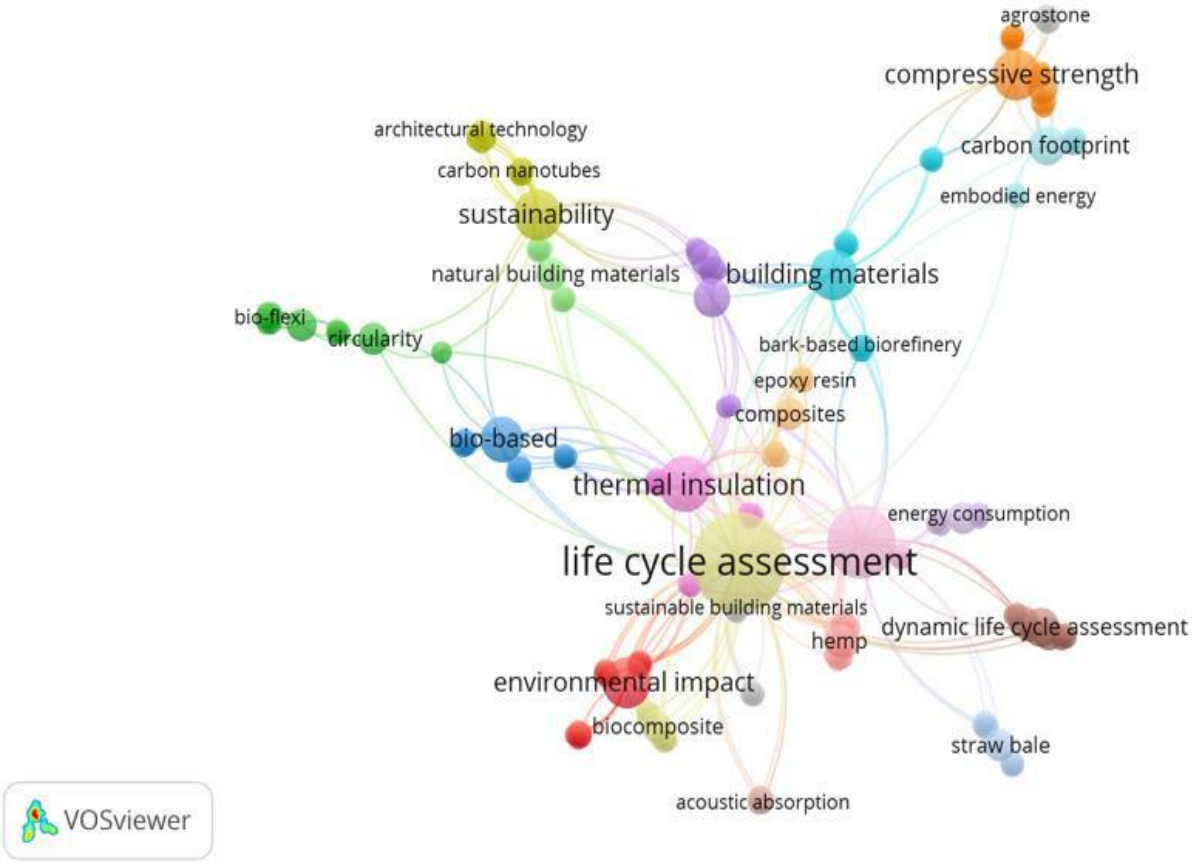

Figure 4. *Author keywords co-occurrence in the published articles of the sample.*

In order to illustrate more precisely the occurrences of keywords, the present study carried out an analysis using RStudio and Biblioshiny tools. Figure 5 shows the most frequent words among the author's keywords. The keywords "life cycle assessment" has the highest occurrences at 19 times, followed by "bio-based building materials" (10 times). The keyword "thermal insulation" has noticeable occurrences six times, indicating that C2BIMs are a popular research object. Moreover, the keyword "environmental impact" (5) plus "carbon footprint" (2) is higher than "sustainability" (5), reflecting that the environmental pillar of the case studies drew more research interest than the other sustainable dimensions or the sustainability. Furthermore, it should be highlighted that the occurrence of the keyword "circular economy" expresses the close link between C3BMs and the CE in the CI.

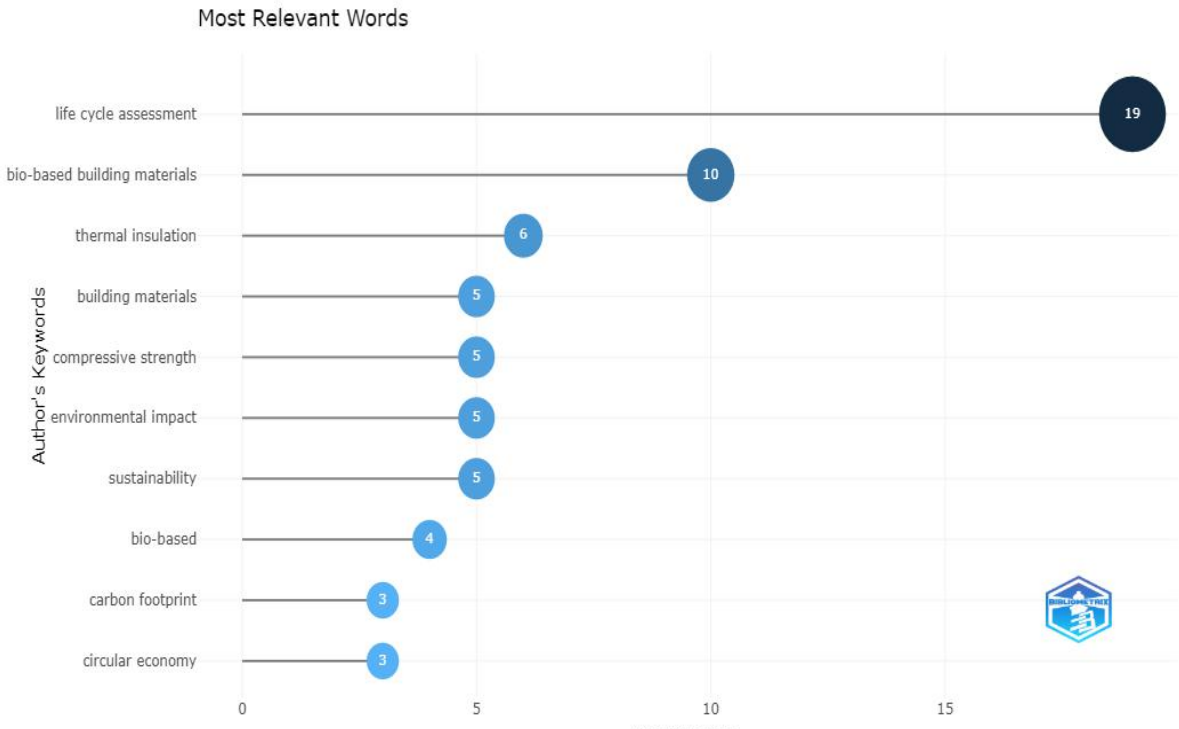

Figure 5. *The most frequent keywords.*

4. Classification and discussion

Literature from selected criteria is classified based on the case studies and assessment methods they have applied. The below sections explain the detailed literature classification accordingly.

4.1. Case studies

Case studies that have been analyzed in the inventoried articles are very heterogeneous. However, they can be divided into four levels: i) C3BMs, ii) building components (e.g., walls), iii) buildings and iv) the building stock. Among these, most works focus on C3BMs, with 26 papers, followed by buildings
and the component level (7). Only two articles consider the building stock level. Plus, it should be noted that Saeli et al. (2022) evaluate both the C3BMs and building levels. The following sections highlight the details for each level.

4.1.1. Circular bio-based material level

The C3BMs are very diverse in type, composition, and usage. For instance, they are diverse from concrete with composition partly derived from coconut shell (Azunna et al., 2019), bio-based biocomposite (Khoshnava et al., 2018; Miller, 2018), etc. Nonetheless, they can be categorized into three main groups corresponding to their using purposes: i) insulation materials, ii) new concrete and binder/filler for concrete and mortar

mixtures, and iii) indoor application materials (e.g., flooring, furniture, and other finishing purposes). The classification details are shown in the following table.

Table 1. *The classification of C3BMs appeared as case studies in collected articles.*

Names of C3BMs	Wholly or partly derived from	Source
Group 1: Circular bio-based insulation materials		
Coconut shell concrete	Coconut shell	(Azunna et al., 2019)
Cork boards	Cork wastes	(Silvestre et al., 2016)
Fired clay bricks	Wheat straw, olive stone flour	(Bories et al., 2016)
Particleboards	Pinus and eucalyptus wastes	(Silva et al., 2021)
Biocomposites	Hemp	(Sinka et al., 2020)
Hemp fiber, flax, and miscanthus	Hemp, flax, and miscanthus	(Schulte et al., 2021)
Linoleum	Plants, pine resin, linseed oil, wood, cork flour	(Rosso et al., 2020)
Composite boards	Flax, hemp, coir, jute, shredded cotton fibers	(Quintana et al., 2018)
Lightweight brick	Oyster shells, rice straw	(Liu et al., 2020)
Bio-based panel	Residual coniferous bark	(Barrio et al., 2021)
Bio-based panel	Pineapple by-products	(Arellano-Vazquez et al., 2020)
Biocomposite	Oil palm fiber	(Khoshnava et al., 2020)
Bio-epoxy composite board	Flax fiber, recycled cellulose, sheep wool waste	(Quintana-Gallardo et al., 2020)
Bio-based wall panels	Wood chips, starch, jute mesh, flax, mycelium	(Cascione et al., 2022)
Mortar	Spent coffee grounds	(Scalia et al., 2021; Saeli et al., 2022).
Group 2: New concrete or binder/filler for concrete/mortar		
Coconut shell concrete	Coconut shell	(Azunna et al., 2019)
Concretes containing rice husk ash (RSH.)	Rice husk	(Garas et al., 2021)
CoRncrete	Corn starch	(Kulshreshtha et al., 2017)
Filler or binder in concrete and mortar	Waste wood	(Doudart de la Gree et al., 2016)
	Potato starch	(Bumanis et al., 2020)
Group 3: Circular bio-based materials used for indoor applications		
Bio-flexi HDF fibreboards	Straw	(Horn et al., 2018)
Woody-like composites	Recycled cellulose	(Platnieks et al., 2020)
Bio-based wood flooring coatings	Corn, soy	(Montazeri and Eckelman, 2018)
Bio-based biocomposite	Hemp linen, jute burlap, hemp burlap textiles	(Miller, 2018)
	Kenaf bast fiber, oil palm fiber	(Khoshnava et al., 2018)
Ultralight particleboards	Wood residues from sawmills and corn	(Ganne-Chédeville and Diederichs, 2015)

As displayed in Table 1, C2BIMs are dominant compared to others. Indeed, 15 articles focus on this category, accounting for nearly 60%. Within these, the insulating materials vary from agro-concrete (Azunna et al., 2019), new kinds of bricks (Bories et al., 2016), and biocomposites (Sinka et al., 2020) to raw materials for developing insulation materials (Scrucca et al., 2020), etc. On the other hand, only a few works take into account C3BMs for indoor applications (6) and new types of concrete, binder/filer for concrete used for structural purposes (5).

It is to be noted that some C3BMs can be utilized for different purposes. For example, coconut shell concrete can be used as insulation material or for constructing structural components (Azunna et al., 2019). Of course, for different purposes, the replaced percentage of fine aggregate by coconut shell has to be different. Likewise, bio-based biocomposite can be installed into buildings for either insulating or indoor applications like flooring (Khoshnava et al., 2018; Miller, 2018).

Regarding the ecological origins of materials, most of the C3BMs here are wholly or partly derived from various agricultural or forestry wastes and by-products, i.e., origin from plants. However, hemp, straws, and cork wastes are mainly applied compared to others. Otherwise, only two works investigate the potential of using animal-related waste or by-products for developing C3BMs, including oyster shells (Liu et al., 2020) and sheep wool waste (Quintana-Gallardo et al., 2020).

4.1.2. Building component level

As mentioned, only seven articles consider the influence of C3BMs on the performance of buildings components. Interestingly, all case studies in these papers are circular bio-based walls. It is understandable because all these works aim to evaluate the potential of using C3BMs to boost the thermal productivity of buildings. More details are depicted in the following table 2.

Table 2. *Details of case-study building elements in collected articles.*

Components	**C3BMs**	**C3BMs derived from**	**Purpose of C3BMs**	**Source**
Miscanthus concrete walls	Miscanthus blocks	Miscanthus	Insulation	(Ntimugura et al., 2021)
Bio-based wall	Wood and straw	Wood and straw	Insulation	(Zieger et al., 2020)
Rice straw wall	Straw	Straw	Insulation	(Quintana-Gallardo et al., 2021)
Hemp concrete wall	Hemp concrete	Hemp	Insulation	(Heidari et al., 2019; Pretot et al., 2014)
Exterior walls	Light clay straw, straw chips, reed mat; hempcrete, hempcrete blocks	Straw, reed, hemp	Insulation	(Pittau et al., 2018)
10 cm thick hollow Agrostone wall	Agrostone	Water Hyacinth, Bagasse, Grass	Insulation	(Degu, 2021)

4.1.3. Building level

Seventeen studies use buildings as case studies, and most of them are residential buildings, except for building-like cubicles presented by Torres-Rivas et al. (2018; 2021). Moreover, the buildings are very heterogeneous in type and location; for instance, a one-story house with brick walls in Italy (Barreca et al., 2019), and a high-rise building in China (Guo et al., 2020), etc. Noticeably, all these buildings utilized C3BMs to boost the insulating performance, i.e., saving energy during the operational phase. Interestingly, sixteen buildings have walls using C3BMs, while the remaining one has the roof installing hemp-plasterboards. Brief information of the buildings, of the C3BMs being used, and other relevant information is shown in Table 3.

Table 3. *The classification of case study buildings in collected articles.*

Type of buildings	Component	C3BMs	C3BMs derived from	Source
A hypothetic one-floor house	Walls	Agglomerated cork; Giant reed	Cork residues, giant reed residues	(Barreca et al., 2019)
Straw buildings	Walls	Straw bale	Straw	(Guo et al., 2020; Krasny et al., 2017)
A single-family house	Walls	Cob; Light straw clay	Cob, straw	(Ben-Alon et al., 2021)
A case study room	Walls	Hemp concrete	Hemp	(Bennai et al., 2022)
A residential building	Roof	Hemp-plasterboard	Hemp	(Charai et al., 2021)
Three reference buildings	Walls	Prefabricated straw bale	Straw	(Yin et al., 2020)
Building-like cubicle	Walls; Roof	Bio-based insulators	Wool, wood, cork, corn, hemp, cotton	(Torres-Rivas et al., 2021)
	Walls	Bio-based insulators	Cotton, cellulose, cork, corn, hemp, wool, wood	(Torres-Rivas et al., 2018)
A building in Iraq	Walls	Bio-based insulators	Reeds	(Simonini et al., 2021)
A two-bedroom residential dwelling	Walls	Hempcrete	Hemp	(Shang and Tariku, 2021)
A virtual building	Walls	Bio-based mortars	Spent coffee ground	(Saeli et al., 2022)
The Val Melaina I complex in Rome	Retrofit walls	Bio-based insulators	Straw and hemp	(Rosso et al., 2021)
An office	Walls	Bio-based composite	Sawdust, palm fibers	(Opoku et al., 2020)
A low-cost house	Walls	Waste-based bricks	Cotton, paper, RSH waste	(Joglekar et al., 2018)
A four-story building	Walls	Latent heat storage biocomposites	Coconut, palm oil, palm and soy wax, rice husk biochar	(Jeon et al., 2019)
A multi-story building	Walls	Hemp-lime	Hemp	(Florentin et al., 2017)

As shown in Table 3, most of the C3BMs installed in the case studied buildings originate from agricultural waste and by-products. Plus, hemp and straws, once again, are two of the most popular biological sources of C3BMs used in these case study buildings.

4.1.4. Building stock level

It can be seen from the sample that the dynamics of using C3BMs at a large level are not yet well known. Indeed, only two papers demonstrate the potential of utilizing C3BMs at the building stock level, according to only 3.9%. In particular, while Göswein et al. (2021) evaluate a new residential building stock, Pittau et al. (2019) take existing housing into consideration. It is understandable because Göswein et al. (2021) consider the context of a city in a developing country with a high demand for new buildings. On the other hand, Pittau et al. (2019) focus

on the European Union Member States context, where more than 80% of residential buildings were built before 1990 (Volk et al., 2014).

Therefore, the focal points of these studies are different.

4.2. Assessment methods

This section discusses the preliminary findings from the analysis of assessment methods applied in the collected articles according to the levels of case studies and the sustainable dimensions. Results are summarized in Table 4.

Table 4. *Methods applied to assess the sustainable dimensions of analyzed case studies.*

Dimensions	Methods	Source	Total
I. The C3BM level			
Environment	Life Cycle Assessment (LCA)	(Silva et al., 2021), (Khoshnava et al., 2018), (Miller, 2018), (Bories et al., 2016), (Sinka et al., 2020), (Silvestre et al., 2016), (Rosso et al., 2020), (Quintana et al., 2018), (Arellano-Vazquez et al., 2020), (Khoshnava et al., 2020), (Quintana-Gallardo et al., 2020), (Cascione et al., 2022), (Kulshreshtha et al., 2017), (Montazeri and Eckelman, 2018), (Ganne-Chédeville and Diederichs, 2015), (Bumanis et al., 2020)	16
	Life cycle inventory analysis	(Platnieks et al., 2020)	1
Economic	Simple cost analysis	(Azunna et al., 2019), (Doudart de la Gree et al., 2016)	2
Environmental and Economic	LCA and Life cycle costing (LCC)	(Schulte et al., 2021)	1
	Carbon inventory and cost-benefit analysis	(Liu et al., 2020)	1
	VIKOR and TOPSIS methods	(Scalia et al., 2021)	1
	Multi-criteria approach	(Saeli et al., 2022)	1
Sustainability	Life cycle sustainability assessment (LCSA)	(Barrio et al., 2021)	1
	Sustainable Decision Support System model	(Garas et al., 2021)	1
	Bio-Inspired sustainability assessment method	(Horn et al., 2018)	1
II. The building component level			
		(Ntimugura et al., 2021), (Zieger et al., 2020) (Alberto	

Environment	Life Cycle Assessment (LCA)	Quintana-Gallardo et al., 2021), (Pretot et al., 2014), (Heidari et al., 2019)	5
	Dynamic LCA	(Zieger et al., 2020), (Pittau et al., 2018)	2
Economic	Simple cost analysis	(Degu, 2021)	1
III. The building level			
Environment	Energy performance assessment	(Barreca et al., 2019), (Bennai et al., 2022), (Charai et al., 2021), (Yin et al., 2020), (Simonini et al., 2021), (Saeli et al., 2022), (Rosso et al., 2021), (Opoku et al., 2020), (Jeon et al., 2019), (Guo et al., 2020)	10
	Life Cycle Assessment (LCA)	(Ben-Alon et al., 2021), (Shang and Tariku, 2021), (Florentin et al., 2017)	3
Environmental and Economic	Multi-objective optimization	(Torres-Rivas et al., 2018)	1
	Energy performance assessment and simple cost analysis	(Krasny et al., 2017)	1
	Combinations merges building simulation, Data Envelopment Analysis, and LCA.	(Torres-Rivas et al., 2021)	1
Sustainability	MultiCriteria decision analysis	(Joglekar et al., 2018)	1
IV. The building stock level			
Environment	Material flow analysis and LCA	(Göswein et al., 2021)	1
	Material flow analysis and LCA	(Pittau et al., 2019)	1

As displayed in Table 4, up to 41 studies assess only the environmental impacts of case studies, accounting for 80.4%. These papers distribute to the C3BM level (19), component level (7), building level (13), and the building stock (2). It is followed by studies that simultaneously consider the environmental and economic dimensions, with four and three papers distributed to the C3BM and building levels, respectively. Only three articles consider the economic pillar individually, with two at the C3BM level and one at the component level. Likewise, only four studies evaluate the sustainability of case studies, three for the C3BM level and only one for a building. No paper that considers the circularity or only the social pillar could be found.

With respect to the methods, it has to be noted that they are very varied. For instance, focusing on the environmental dimension, five different approaches have been implemented to evaluate the environmental impacts of C2BSs, and their contribution is depicted in Figure 6. It can be seen that the LCA is the most exploited method, exhibiting 61%, followed by the energy performance assessment with 26%. Other methods altogether accounted for only 13%.

On the other hand, for assessing the economic aspect, all three papers use the simple cost analysis, while various methods have been utilized to analyze both the economic and environmental pillars or the sustainability of C2BSs. However, the majority of these methods are proposed by authors based on the multi-criteria approach. For instance, this approach has been applied by Joglekar et al. (2018), Saeli et al. (2022), and Torres-Rivas et al. (2018). Nonetheless, it should be noted that these methods are applied individually in each research study, and the potential for their wide application may be limited.

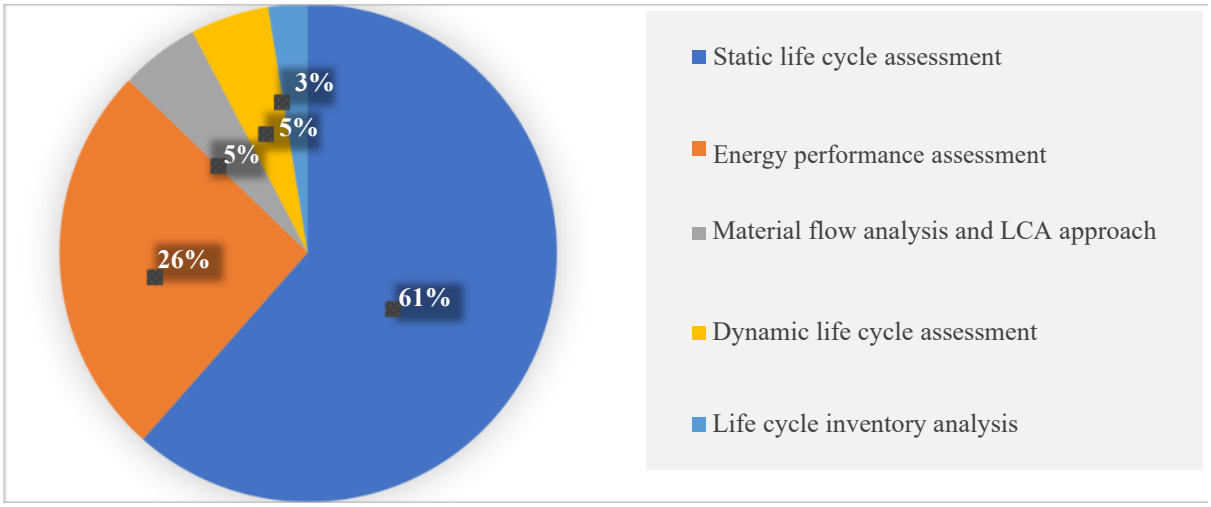

Figure 6. *Methods exploited to evaluate the environmental dimension.*

5. Conclusion

Summing up the conducted literature analysis allows the present study to answer the research questions. Indeed, this study focused on two significant objectives, using a systematic literature review and bibliometric analysis. The first was to classify case studies in the analyzed articles related to C3BMs and their sustainability assessment. To achieve the first objective, the present study proposed a specific definition of circular bio-based material in general and C3BM in particular because these could not be found in the extant literature. Afterward, the eligibility criteria were proposed to focus only on relevant studies on the research topic. Conducted research showed quality work in assessing the environmental sustainability of C3BMs and their influence when being used in buildings. Economic dimension, social pillar, sustainability, and the circularity assessment of C2BSs were also part of the review. The case studies were classified into the related levels, including C3BM, component, building, and the building stock level. Most of the past research focused on the C3BM level, followed by the building level and building component level. On the other hand, the building stock level was less common. Moreover, most C3BMs appeared in the case studies are used for insulating purposes.

The second objective of this research article was to review the methods used to evaluate the sustainable aspects of C2BSs at different levels. The results indicate that the past research was mainly distributed to the environmental impact assessment of products. It is followed by works assessing economic and environmental dimensions or only economic performance. Only four records were attributed to assessing case studies' sustainability, three for C3BMs and one for the building level, respectively. Regarding the approaches used to evaluate the environmental dimension, LCA is the most popular and mostly applied in the C3BM and building component levels. For the building level, energy performance evaluation using commercial software is the most used approach. On the other hand, most studies evaluate the sustainability of case studies using their own proposed methods, except utilizing the life cycle sustainability assessment method. No work taking into consideration only the social aspect or the circularity of C2BSs could be found in the literature.

However, this study considered only literature extracted from the WoS and SP. Plus, the analysis of assessment methods is just in the preliminary phase. Future research should expand data sources and focus on critical discussion of the methodological aspects of methods used to evaluate the sustainable aspects of C2BSs. Furthermore, further study should point out the pros and cons of using C2BSs in the construction industry.

Circular Economy Practices in the Agri-food Sector: A literature review

Federica Scandurra[1], Roberta Salomone[1], Sandra Caeiro[2], Giovanni Mondello[1]

[1]Department of Economics, University of Messina, Italy
[2]Department of Science and Technology, Universidade Aberta, Lisbon, Portugal

Abstract

The Agri-food sector (AFG) is now facing relevant challenges. Population growth is increasing global food demand, despite hunger and poverty are far from defeated. The AFS has a crucial role in promoting human wellbeing by ensuring fair access to food and water. To do so, the sector must address environmental issues, thus a conversion towards sustainability is needed. In the last decade, circular economy (CE) has drawn worldwide attention as a powerful tool to implement sustainable development (SD). CE promotes a cyclical model, in which waste becomes resources and efficiency is maximized. Thus, CE might be the right solution for restoring the AFS, aligning its production and consumption models to sustainability. In literature, there are several examples of CE implementation in the AFS. Nevertheless, CE's sustainability in this sector is far from assessed. SD indeed requires addressing challenges from an economic, environmental, and social point of view., if circularity is not able to do so it could exacerbate the planet-people nexus. The present study aims to explore the inter and intra company experiences of circularity in the AFS, adopting empirical case studies as the unit of analysis and a micro and meso perspective. The investigation emphasizes the characteristics of circular activities, classifying them in terms of process and goals, as well as the level of innovation. Finally, it is examined the link of CE implemented in the AFS with other sustainability narratives. The study presents a bibliometric analysis of the existing scientific literature extracted from the databases Scopus and Web of Sciences (WOS), covering the time frame 2015-2021. This enables to understand how the topic has evolved after the introduction of the European action plan for CE (EU,2015). The analysis allowed to establish a database of CE activities and best practices of the sector, promoting awareness on the topic, stimulating new insights and perspectives, and encouraging practitioners to implement circularity solutions in the AFS. the analysis contributes to several Sustainable development goals (SDGs), especially number 12, which promotes responsible production and consumption models and number 2, which encourages initiatives to ensure zero hunger.

Keywords: Circular economy, Agri-food sector, Sustainable development, Bibliometric analysis

1. Introduction

The agri-food sector (AFS) has a central role in the actual worldwide productive context primarily because it relates to obtaining and distributing the primary source of livelihood for mankind: food. Despite its centrality, this sector is not exempt from the aggressiveness of the linear paradigm -take, make, waste- which causes, only in Europe, 700 million tons of waste every year, affecting the environment and threatening the biodiversity of the ecosystem (Fortunati et al., 2020). At the same time, the AFS is characterized by the so-called "food paradox", namely having food waste in a world still affected by food insecurity (Ciccullo et al., 2021). Indeed, Food Losses and Wastes (FLW) represent 25% of food production worldwide (Fassio and Tecco, 2019). By FLW it meant any reduction in quantity or quality of food resources along the value chain. In particular, food loss occurs from the harvest to the retail phase, whereas food waste occurs from retail to consumption (FAO, 2019). The current scenario is further challenged by the population increase expected for 2050 when the global production system is going to deal with 2 more billion people's food demand (Toop et al., 2017).

To face such challenges, the AFS needs a new root, which is environmentally, socially, and economically sustainable in the long term. In the last decade, the Circular Economy (CE) has gained global attention as a valuable tool to reach sustainable development (SD) (Kirchherr et al., 2017). CE is based on the concept of "eco-efficiency", which minimize input use and waste production by improving the efficiency of productive systems (Ghisellini et al., 2016). It can be implemented at various levels: macro, when dealing with cities, regions, or countries; meso, when considering eco-industrial parks or symbiosis networks; micro, when involves companies or products (Ghisellini et al., 2016). The implementation of CE in the AFS is ancient, indeed circularity principles were embodied in the agricultural dynamics even before the term was coined. Such practices were considered simply resource economy measures, before being recognized as circular (Fassio and Tecco, 2019). This suggests that the AFS is potentially mature in terms of CE application, thus it is relevant to comprehend how circularity is practically operated and embodied in the food system. To do so, case studies should be used as a measure of analysis, to find exhaustive descriptions of CE practices and capture their value and main features. In addition, considering that CE dynamics and synergies are present both at intra-and inter-company levels, both levels of analysis should be considered: the first dimension can be evaluated by analysing the characteristics of single organizations through a micro perspective, while the latter by considering the inter-firm dynamics employing a meso perspective, configured as Industrial symbiosis (IS). Furthermore, CE and IS have as their primary goal to reach SD, this makes it relevant to understand if these practices and exchanges are first sustainable in the long term for the environment, the society and the economy. In this context, several reviews explore the implementation of CE principles in the AFS (Esposito et al., 2020; Hamam et al., 2021; Chiaraluce et al., 2021; Barros et al., 2020; Stilitano et al., 2021). Nevertheless, these studies do not examine the whole AFS and do not

examine the inter and intra-business synergies in detail, considering the adherence to sustainability narratives.

Given this lack in the literature, the proposed research focuses on the meso and micro level of circularity by addressing the research question (RQ) and sub-questions: What kind of Circular Economy practices and experiences are present in the agri-food sector at meso and micro level? a) Are these circular practices innovative or traditional? b) Are these circular practices in line with the concept of sustainability? c) Are these circular practices related to other sustainability narratives, such as industrial symbiosis? If yes, what is the link between circular economy and industrial symbiosis in the food sector?

The study here presented shows only the preliminary results of the literature review analysis conducted in the proposed research. Here it is described the systematic protocol applied to determine the sample of articles and the bibliometric analysis carried out to map the scientific knowledge, evaluating the evolutionary trend of the field (Donthu et al., 2021). The complete analysis, as well as the methodological issues identified, will be discussed in future publications.

2. Methods

The present study does not answer all the RQs previously mentioned but allows for a partial answer to the first sub-question. Bibliometric analysis was chosen as a research tool for its capacity to map systematically research outcomes. It enables us to analyse how the research interest of the topic has spread, evaluate the time trend of publications, the journals most interested in the research field as well as capture the multidisciplinary nature of the CE, which interests journals with very different areas of interest. Bibliometric information is thus essential to frame the phenomenon under evaluation in specific space-time coordinates, generating a solid base for following systematic analysis.

The consistency and robustness of the present study are guaranteed by the adoption of a systematic protocol articulated in a) identification of the articles according to the information in the title, abstract, and authors' keywords; b) application of exclusion first and eligibility criteria after to consider the studies in line with the aim of the research; c) collection of the articles found; d) discussion and synthesis of the results of the analysis. Scopus and Web of Science (WOS) databases were selected to identify and collect contributions in line with the research question of the study, given the quality of articles included in such databases. The analysis was carried out by using a combination of Boolean operators and keywords linked to the AFS, in all the possible written forms, CE and case studies. The present analysis was performed on 31 December 2021. To refine the search process some exclusion criteria were adopted. The primary criteria identified were the timing of the analysis, the typology of contribution, the publication stage, as well as the area of research and the language. The starting point of the analysis is 2015, given the introduction of "Closing the Loop: An EU Action plan for the Circular

Economy Package" by the European Commission (EC, 2015) in the same year. Afterwards, all the duplicates were selected and deleted. Then secondary exclusion criteria were identified and applied. Information regarding title, abstract and keywords was analysed to understand which studies were in line with the research question Afterwards, the full-text evaluation of the articles of the sample was performed. At this stage, some eligibility criteria were selected to refine further the spectrum of analysis. The final sample includes 42 contributions. The research procedure followed by the study is illustrated in Figure 1. To summarize the research evidence, the bibliometric analysis was performed classifying information according to the publication period, journal and research area covered by the journal. The first enables to identify any possible trend or discontinuity in the publication rate of the field. The second allows to determine which journals contribute more to the topic, finally exploring the journals' research are it is possible to understand which areas and subjects are interested in circularity in the AFS. In addition, systematic information regarding the geographical context of the study is included to understand where these practices are settled, and which areas or countries are involved.

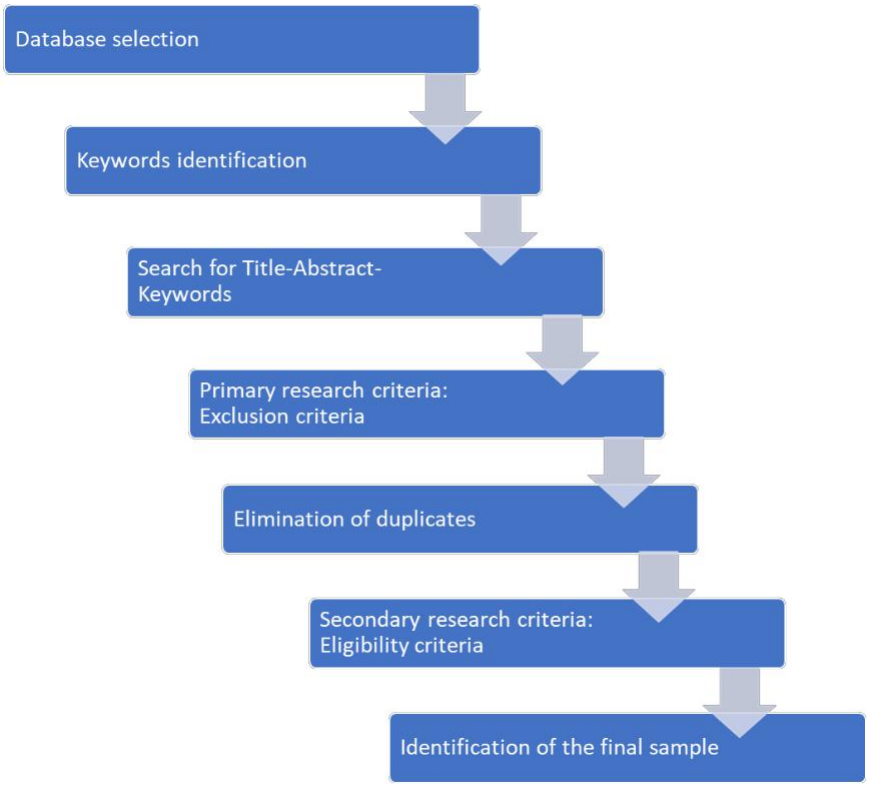

Figure 1: Literature search procedure diagram.

3. Results and Discussion

Considering the publication period, 42 contributions were identified over 2015-2021 according to the present criteria of research. From a chronological point of view, the contribution pattern is unstable from 2015 to 2017. Indeed, in 2015 3 articles were published on the topic, while in 2016 only 1 study is present (Maaß and Grundmann,

2016). The trend is growing again in 2017, thus 2016 can be considered an exception, probably linked to the eligibility criteria selected for the study. The following 2 years, namely 2017-2018, present a slight increase of 1 unit in the number of publications, which remains stable. The real turning point is the two years 2020-2021. Comparing 2020 with 2019 the number of publications is more than doubled. 2021 shows the highest number of contributions in absolute terms, publishing 15 articles. This confirms that there is increased attention on the CE in the agri-food context in the period under analysis. Nevertheless, the pattern shows consistent discontinuities, which make it difficult to assess a clear forecast for the future of the area. One possible explanation could be that the pandemic has raised more awareness of the insecurity and fragility of the food sector, encouraging scholars to move their attention to sustainable and circular solutions for such a key sector. Anyway, it is hoped that contributions such as the SDGs at the international level and the European Green deal (2019), through the Farm to fork strategy (EC, 2020) will boost and sustain the international interest in the topic.

Moving to the analysis of the journal source, 24 peer-reviewed journals published contributions to the argument. The full list of journal source contributions per year is presented in Figure 2. Considering that the sample includes 42 articles, the number of journals seems significant. The largest contributor in this field is the “Journal of Cleaner Production”, which published 10 articles on the issue. The distribution of publications for this journal is irregular from 2015 to 2019, (no studies were published in 2016 and 2019) but constant in the last two years, contributing to the topic with 2 and 4 articles respectively in 2020 and 2021. Afterwards, “Science of the Total Environment” and “Resource, Conservation and Recycling” published 4 studies each. The first contributed only in 2020 and 2021, with 1 and 3 articles, while the second one was the only journal to publish in 2016 but shows no publications in 2021. As already stated, the number of journals is relevant, indeed 18 out of 24 Journals published just one article. This suggests the fragmentation of the sector, thus the AFS is approached with different views and perspectives, it is not linked to a specific journal or set of journals, but it is quite spread.

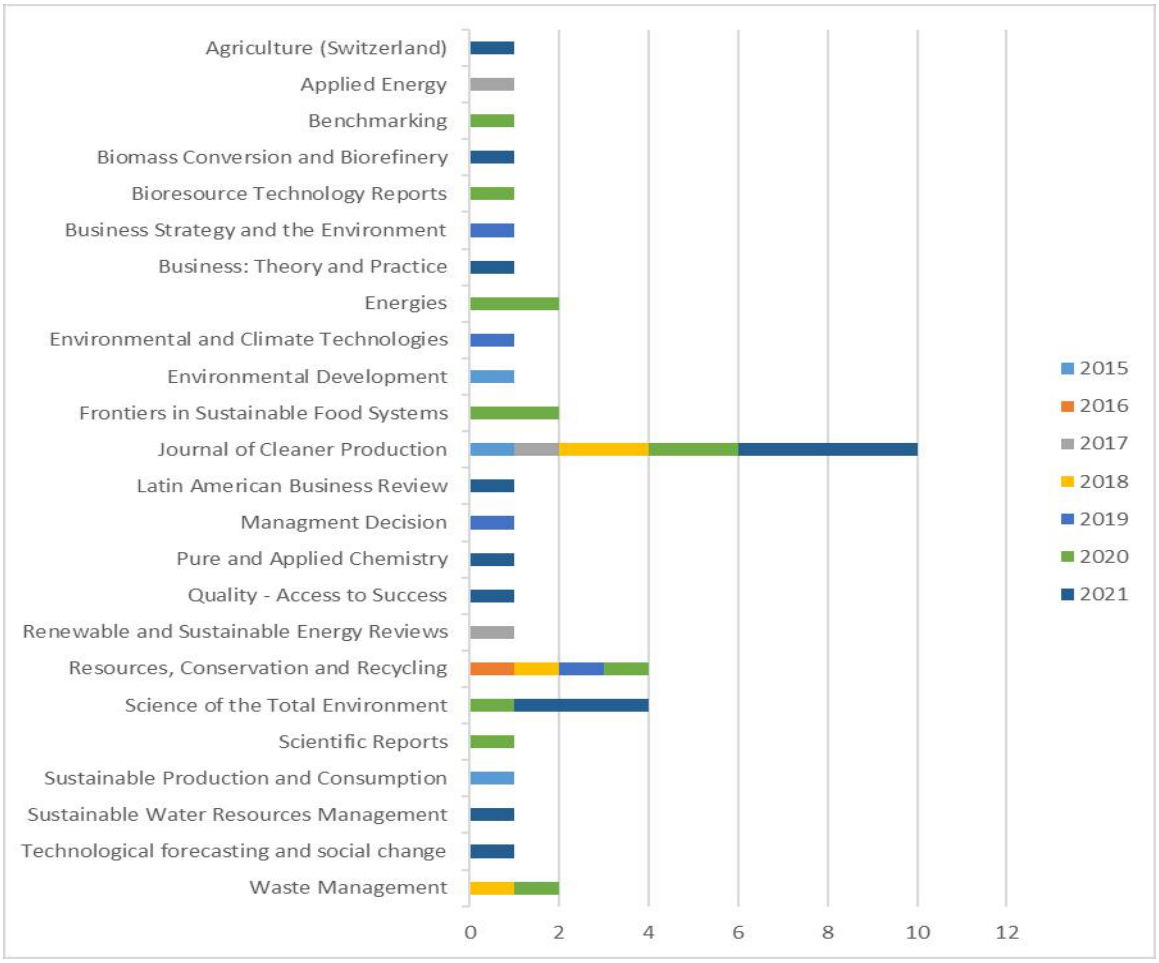

Figure 2: Number of contributions per journal and year about CE in AFS, according to the defined criteria.

Finally, by identifying the research area covered by the single journals it is possible to study the areas more interested in the topic and try to motivate the fragmentation encountered. Figure 3 indicates the most frequent research areas in the sample of journals analysed. At this stage, it is relevant to remember that the number of areas identified by this analysis does correspond to the number of articles included in the sample, given that a single journal may work on different research areas. The most relevant area of research is "Environmental Science", which represents 11 out of 46 units. Afterwards, "Energy" represents the second most important area, referring to 8 journals. Then, "Business, Management and Accounting" describes 5 journal areas of interest. Thus, the strong environmental vocation of the topic is clear, often directed to finding alternative energetic solutions that combine food waste and residues into renewable forms of energy. Nevertheless, an economic interest, especially in managerial terms, is present, probably to understand how to account and measure these practices or to offer

guidance to companies that are willing to start a path toward circularity. In general, the topics covered by the journals are various and spread from phycology to econometric and social sciences.

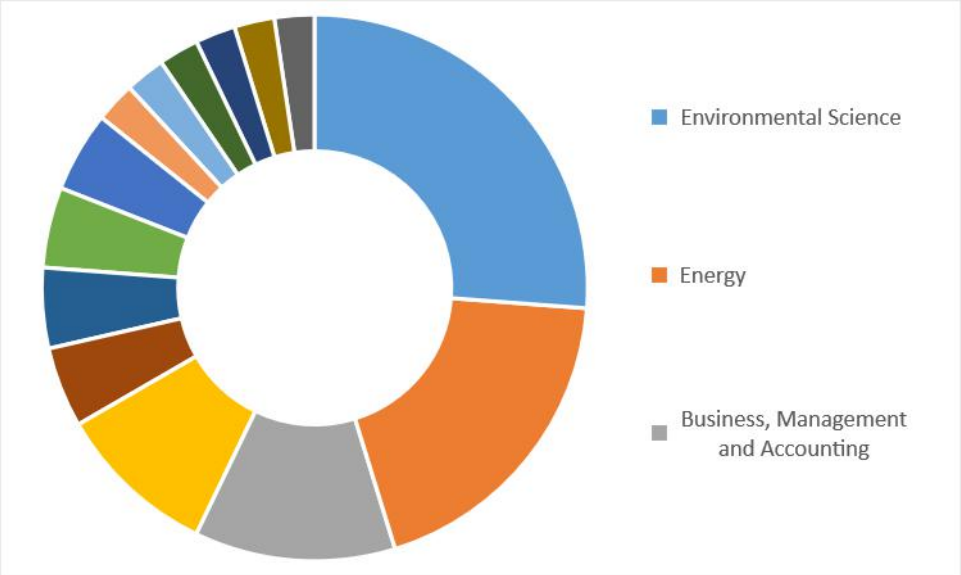

Figure 3: Research area per journal about CE in AFS, according to the defined criteria.

Moving to the geographical setting of the studies, 45 countries were identified. In Figure 4 the distribution of articles' setting per continent and country is shown.

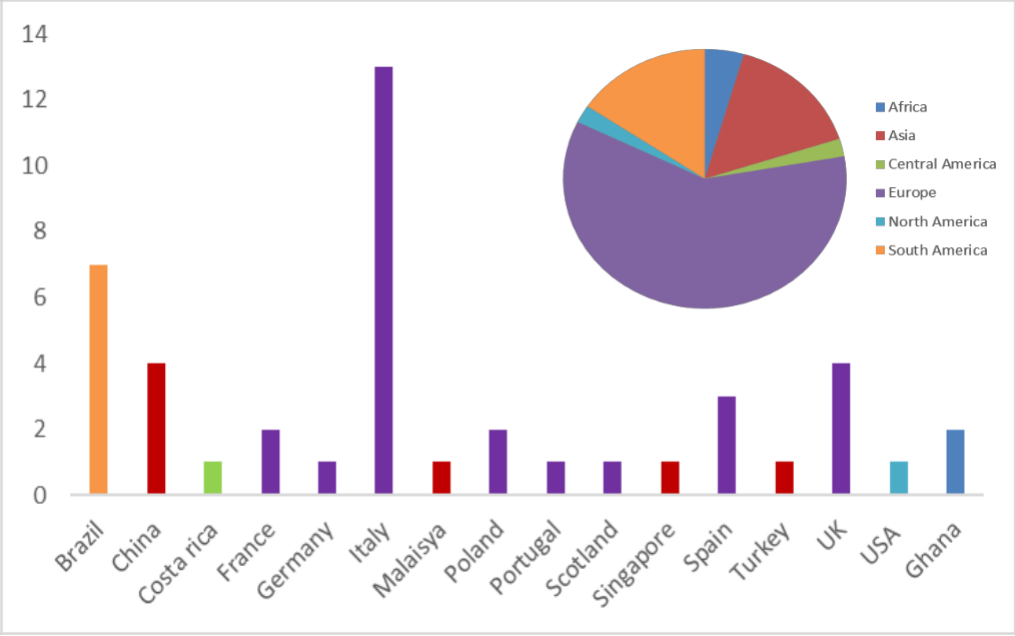

Figure 4: Geographical setting of the studies in terms of country and continent according to the defined criteria.

Some multi-country studies were encountered: Brazil-United Kingdom (De Vasconcelos et al., 2021), Italy-Spain (Jiménez-Benítez et al., 2020) and Egypt-Ghana (Patrizi et al, 2020). Only the first study undertakes a collaboration between companies of the two countries, exploring the fresh fruit supply chain to reduce FLW, exploiting stakeholders' desire pressure for sustainability. In general, European countries and areas are the most interested in implementing CE solutions in the AFS, representing 60% of the countries involved in the sample. Italy presents the highest number of studies with 12 contributions, followed, with a considerable distance, by Spain with 4 contributions on the topic. After Europe, Asia and South America represent both the 16% of the study setting. The presence of Asia among the most common continents for CE implementation does not surprise, given that China was the first country to introduce CE as a national policy (PRC, 2008). Most Asian studies indeed involve China, nevertheless, there are contributions on the topic also from Singapore, Turkey, and Malaysia; thus, CE is not exclusively a Chinese policy, and it is now spreading over Asia. Despite China's leading role in the adoption of CE, its interest in the AFS application is stable, but no growing trend was observed in the last two years. China presented indeed studies on the topic in 2015 (Yu et al., 2015), but no articles were settled in the country in the last two years. Two years are not enough to define if the country's interest is in decline, nevertheless, the country may have moved its attention to another sector for CE. South America, precisely Brazil, is a relevant contributor to the AFS. It presents a wide variety of studies, moving from sharing economy practice in rural communities (Rodrigues et al., 2021), to strategies of value recovery for large businesses (Sellitto and Almeida, 2019), or examples of waste recovery solutions on university campuses (De Sousa et al., 2021), showing interest on the topic from different perspectives and levels of agglomeration. Among the non-European countries, Brazil shows the highest number of contributions. Analysing the temporal trend of such studies, they were all published in 2020-2021, precisely 1 in 2020 and 6 in 2021. This demonstrates the increased interest in the topic as well as how much CE is spreading globally. The outcomes of the present study will be further discussed in a future contribution, which will allow answering all the RQs presented in the introduction section by conducting a systematic literature review, supported by content analysis techniques.

4. Conclusions

Since 2015, the AFS has progressively increased its attention toward circularity. Even if at the beginning unsteadily, the last two years demonstrate the growing awareness shown by businesses and organizations in the sector. A wide variety of journals are interested in the field, especially those focused on environmentally and energy topics, together with others interested in managerial insights. From a geographical point of view, European areas are the most interested in implementing CE as a guide for their food system. Mediterranean countries, such as Italy and Spain are the most committed to the cause, trying to direct their food production systems towards sustainable

development. Among the non-European countries, Brazil presented the highest number of contributions, involving a variety of stakeholders and perspectives of analysis. This demonstrates that the interest is growing both in terms of publication and countries, CE has now reached a global scale and this tendency is going to increase in the following years, especially considering the level of increase registered by the present study. Implementing CE in the food context is necessary to promote a real transition to SD, given the social role of the AFS, which express human interactions with the environment. This paper presents some limitations due to the choice of specific keywords and the time limits imposed, nevertheless, it gives a clear idea about how the AFS is evolving in terms of CE, the temporal pattern, the source of the journal more interested, the subject areas that are now expanding their interest to CE as well as the territories that already exploit CE solutions in their food systems.

Circular Indicators for Agri-food Sector: Test and validation

Prof. Alessandro Ruggieri, Prof. Stefano Poponi, Prof. Gabriella Arcese, Dr. Francesco Pacchera

Università degli Studi della Tuscia, Viterbo, Italy

Abstract

The complex agri-food system is at the core of the transition process undertaken by the European Union towards a climate-neutral, resource-efficient, and competitive economy. Therefore, pursuing a more sustainable and circular production system will bring economic, social, and environmental benefits, balancing the negative impacts generated by this sector. The transition to a sustainable and circular production and consumption model is not only an opportunity, but a necessary direction to follow through a guided path to manage change. This requires a monitoring system to measure progress through the application of Circular Economy principles. However, these tools need to be systematized to ensure that they can be more easily identified and applied to the specific field. There are many heterogeneous indicators for measuring the Circular Economy in the literature and few tools to support measurement in different application contexts. In previous research, we identified a Dashboard of circular indicators for the agri-food sector that combined the three areas of sustainability (economic, social, environmental), the spatial dimensions (micro, macro, meso), and the scopes (air, soil, energy…) in which they fall. The indicators were extracted from the scientific and grey literature on the Circular Economy in the agri-food sector and systematized within it. Starting with this Dashboard, the paper aims to test a selected number of circular indicators within scope, to evaluate the validity of the tool, and the related strengths and weaknesses of its application. The work highlights the implications for the researcher, policy maker, and manager regarding the use of this tool, as well as the future step of the research deriving the opportunity to define new indicators in the selected scope.

Keywords: Circular Economy, Agri-food, Indicator, Cross-sectional, Energy

1. Introduction

The transition to a sustainable and circular production and consumption model is not only an opportunity, but a necessary direction to follow through a guided path to manage change. The agri-food system is at the core of the transition process undertaken by the European Union towards a climate-neutral, resource-efficient, and competitive economy (European Commission, 2020). Therefore, pursuing a more sustainable and circular production system will bring economic, social, and environmental benefits, balancing the negative impacts generated by this sector (FAO, IFAD, UNICEF, WFP, & WHO, 2020). The over-consumption of natural resources, such as soil, energy,

and water, combined with the increasing use of chemicals (such as pesticides and fertilizers), generates significant environmental impacts with economic and social repercussions. Environmentally, the sector is responsible for 30% of Europe's greenhouse gas emissions (Crippa et al., 2021), and is a key player in soil and water pollution (accounting for 32% of global terrestrial acidification and 78% of global eutrophication) (Poore & Nemecek, 2018), and contributes significantly to the consumption of natural resources (30% of global energy consumption and 70% of global water withdrawal) (FAO, 2011b; Flammini, Puri, Pluschke, & Dubois, 2014). Another key issue is food waste, this contributes to the increase in environmental impact, generation of emissions, and consumption of resources (soil, water, energy), and has strong economic and social repercussions (UNEP, 2021). Considering the European food supply chain, it is estimated that 20% of agri-food production is wasted (Stenmarck et al., 2016).

To reduce these impacts and shift the agri-food production model toward more sustainable practices, it is necessary to implement the principles of Circular Economy (CE) (S Poponi et al., 2021; Velasco-Muñoz, Mendoza, Aznar-Sánchez, & Gallego-Schmid, 2021). This requires a monitoring system to measure progress through the application of CE principles, according to different areas and dimensions, and at each stage of the life cycle (ICESP, 2018). In the literature Elia, Gnoni, & Tornese (2017) highlights that system transition requires a model based on measurement tools. A database is needed to interpret changes in trends, aid understanding of the data, or intervene with policies aimed at stimulating circularity (Ruggieri, Braccini, Poponi, & Mosconi, 2016). Saidani, Yannou, Leroy, Cluzel, & Kendall (2019) associate the availability of appropriate and effective measurement tools with the ability to stimulate circular transition. Useful to support decision-makers (Cristóbal, Castellani, Manfredi, & Sala, 2018; Peña et al., 2021; Tadesse, Oenema, van Beek, & Ocho, 2019) and to identify criticalities at different production stages and strengths to invest in (Genovese, Acquaye, Figueroa, & Koh, 2017; Vasa, Angeloska, & Trendov, 2018).

However, these tools need to be systematized to ensure that they can be more easily identified and applied to the specific area. In the literature, there is not yet a defined framework for the use of indicators to monitor and measure CE across the different application dimensions. This gap is especially highlighted in the agri-food sector (Aznar-sánchez et al., 2020), characterized by a very complex value chain with several stages and actors (Notarnicola, Hayashi, Curran, & Huisingh, 2012; Notarnicola et al., 2017). To solve this gap, a Dashboard for the use of circular indicators in the agri-food sector was proposed in a previous study (Stefano Poponi, Arcese, Pacchera, & Martucci, 2022). It is the first reference framework for the application of indicators within the sector. A tool for companies to monitor the management system with a circular approach and at the same time a tool to support policymakers to guide them in stimulating the economic, social and environmental system toward the CE.

Starting with this Dashboard, the paper aims to test a selected number of circular indicators within a Scope, to evaluate the validity of the tool, and the related strengths and weaknesses of its application. The Scope “Energy”,

which considers indicators for energy performance, was selected for the test. This selection is motivated by the important role of energy consumption in the Agri-food sector. The Food System consumes about 30% of available energy globally, where most of the resources come from fossil sources (FAO, 2011a; Flammini et al., 2014). This significant dependence of the sector on non-renewable primary energy sources (e.g. oil, gasoline) generates uncertainty in supply (e.g. price volatility) and high GHG emissions (Monforti-Ferrario et al., 2015; OECD, 2017). For this reason, the study is an important first step in assessing the applicability of the circular indicators proposed by the dashboard in the agri-food Energy Scope.

The paper is organized as follows: the next section describes the method used, section 3 discusses the results of the study, and the last section presents the conclusions and implications of the work.

2. Methods

The study identifies and systematizes the indicators used for the CE in the agri-food sector based on an analysis of the scientific and grey literature. There are several definitions of CE, in this study, the definition of Kirchherr et al. (2017) is taken as a reference. For Kirchherr et al. (2017) CE can operate at the Macro level (nations, regions), at the Meso level (symbiosis), and at the Micro level (companies, products) and create economic, social, and environmental value. The Dashboard proposed combines the spatial dimensions (SD) (Micro, Macro, Meso) and the three Areas of sustainability (AS) (Economic, Social and Environmental) for the Scopes within which the indicator is applied (Air; Water; Soil; Energy; Waste; Cost-Value-Productivity; Equality; Knowledge and Innovation). It is a tool that highlights the gap in the literature (the lack of indicators for areas) and the presence of *Cross-sectional* indicators. These last indicators can be applied indiscriminately within the dashboard in the three Spatial dimensions (SD), for each Area of Sustainability (AS) (Stefano Poponi et al., 2022).

Based on Kirchherr's definition and the structure of the Dashboard, indicators related to the Scope "Energy" with *cross-sectional* characteristics were extracted. This allowed for the identification of four indicators as followed and included in Table 1.

The *Use of primary energy (PE)* indicator (1) quantifies the primary energy needed to produce a product or the entire production chain, considering renewable and non-renewable sources.

The *Use of primary renewable energy (PER)* indicator (2) quantifies the amount of primary energy from renewable sources needed to produce a product or the entire production chain.

The *Use of primary non-renewable energy* (PENR) indicator (3) quantifies the amount of primary energy from non-renewable sources needed to produce a product or the entire production chain.

The *Cumulative Energy Demand* (CED) indicator (4) allows for quantifying the amount of direct energy (conventional sources) and indirect energy (derived from the processes e.g. for fertilization, the use of pesticides, or machinery) needed to produce a product or the whole production chain.

The reference geographical area is Italy, where the agri-food sector is extremely competitive (CREA, 2021). The sector characterizes the entire economy of the country concerning the typicality of the productions, highly specialized, with an important role within the European market (FoodDrinkEurope, 2021).

Three case studies for Macro and Micro SD were used for the analysis. At the Macro level, Italy and the Lazio Region were selected. Lazio Region was selected for its agri-food position in the national economy and because the sector is included in the Smart Specialisation Strategy (S3) areas (Regione Lazio, 2016). Secondary data were extracted from reports and databases and collected through documentary analysis (Fitzgerald, 2012). In particular, at the Italian level, data from the National Energy Balance carried out using the Eurostat methodology were used (Ministery of Ecological Transition, 2018), and converted to MJ where appropriate. At the regional level, the data come from the Regional Energy Balance, converted into MJ, but referring only to the agricultural sector (ENEA, 2018, 2020, 2021). It was not possible to extract or define an allocation system to attribute the data to the whole food supply chain, so the reference area considered is agriculture.

The most complex indicator, the *Cumulative Energy Demand indicator (CED),* uses energy conversions extracted from literature (Biondi, Panaro, & Pellizzi, 1989; Jarach, 1985; Zucaro, 2011). The ISTAT database was used to extract data from the consumption of pesticides and fertilizers (ISTAT, 2021a, 2021b). In calculating the indicator, at the macro level, it was not possible to consider machinery, as the last updated data dates to 2002 and is therefore not usable (FAOSTAT, World Bank).

At the micro level, a micro-sized company was selected, operating in the Lazio region and specializing in the cultivation of durum wheat. The farm was selected for its ease of primary data extraction, thanks to its production focus, small size, and monoculture practice. The choice of the type of cultivation derives from the vocation of the Italian territory, which sees its main vocation in the production and consumption of pasta. Data collection was carried out through a structured interview with the owner of the company (Corbetta, 1999; Eisenhardt & Graebner, 2007).

The reference years for identifying micro-trends are 2015, 2018, and 2019. The most recent data for national or regional indicators are for 2019. The year 2015 represents the benchmark of the old European programming against the subsequent new strategy resulting from the European Commission's first Action Plan for the Circular Economy. The time comparison allows us to observe the impact that these policies have had on the

selected indicators. For the company the year 2015 is technically no longer available (as the company is not obliged to keep records).

Table 1. *Cross-sectional indicator in the Energy Scope.*

Dashboard Scope	Code	Cross-sectional Indicators	Unit of measure	Spatial dimensions Micro - Meso - Macro Areas of sustainability
Energy	1	Use of primary energy (PE)	MJ	
	2	Use of primary renewable energy (PER)	MJ	
	3	Use of primary non-renewable energy (PENR)	MJ	
	4	Cumulative Energy Demand indicator (CED)	J/year	

3. Results and Discussion

The study has tested and evaluated the *cross-sectional indicators* of the Macro and Micro spatial dimensions, for the area of sustainability 'Environmental', regarding the Scope 'Energy'. This has allowed us to understand energy performance, considering the energy inputs required for production, from the use of primary and secondary data, and generally assess the applicability of the Dashboard as a reference tool for circularity.

At macro level, the results allowed a comparison between two levels of analysis, national and regional. The results show a homogeneous trend in the indicators over the considered period. In particular, the PER indicator shows substantial stability. Nationally, it recorded a small decline in 2018, only to rise again in 2019. At the regional level, although it is not possible to detect the trend in 2018, it shows a situation of stability over the period considered.

The PENR indicator, at the national level, increases by 4% in the year 2018, to decrease again in the following year by about 5%. At a regional level, the indicator shows the same trend, but with more pronounced data. Indeed, from 2015 to 2018, the use of non-renewable primary energy sources increases by 54%, only to drop by 19% in the following year.

The PE indicator cumulates the results of the two indicators PER and PENR, expressing the energy requirements of the agri-food system. The national data shows a fluctuating trend, peaking in the year 2018 and then falling in the year 2019. Considering the period 2015-2019, the figure is stable, with a small decrease of 1%. It is on a regional level that the data is most significant, indeed in the period 2015-2019 the energy demand of the regional agricultural sector increases by 24%.

The analysis in the macro dimension at the national level does not show large deviations, it is at the regional level that the most marked variations are recorded. Lazio Region has a strong vocation for agri-food and has started a process of revising its Smart Specialisation Strategy (S3) through a repositioning of high-value-added production activities. Although the PER indicator remains constant over time, the PENR indicator has a marked increase in 2018, and then falls significantly in 2019. The effect of this change is partly attributable to the eco-investments in green products and technologies carried out within the Lazio Region in the period 2015-2019, involving more than 40,000 companies (Regione Lazio, 2020). This shows how the sustainability-oriented policies of organizations can significantly affect the values of energy indicators. The stability of the national indicator hides important variations at the regional level. Therefore, defining a permanent monitoring system of these indicators will contribute to and highlight energy deviations from the various regional policies implemented, allowing intervention with direct policies aimed at compensating for any imbalances.

The national Cumulative Energy Demand indicator (CED) shows an overall reduction in indicator values of about 3%. This was mainly due to a reduction in the indirect component (indirect energy) derived from the processes for fertilization, the use of pesticides, or machinery (ISTAT, 2021a, 2021b). Also, in this case, the year 2018 is linked to a gradual increase of 3% and a subsequent reduction of 6% in the year 2019. At the regional level, the situation shows an overall increase of 8% over the whole period. The most significant regional variations, as for the other indicators, are for the year 2018, with a 27% increase (10 times the national figure) and a 15% decrease in 2019.

The CED and PE results at the Micro level do not show any significant differences over the period considered. This is due to a continuity in the type of cultivation practiced and the related agronomic production techniques. The most significant aspect observed at the micro level, which is not directly observed, is the volatility of fertilizer and energy prices. This aspect has a direct impact on the sustainability of the entire business management system, against indicators that remain constant over time such as PE or CED. It requires the application of direct policies aimed at mitigating the effects of using non-renewable energy sources, which have direct repercussions on product prices or in the most extreme cases on the survival of the company.

Table 2. *Cross-sectional indicator in the Energy Scope in Italy.*

Scope Dashboard	Cross-sectional Indicator	Unit of measure	2015	2018	2019
Energy	Use of primary energy (PE)	MJ	1.48E+11	1.53E+11	1.46E+11
	Use of primary renewable energy (PER)	MJ	4.14E+09	4.11E+09	4.15E+09
	Use of primary non-renewable energy (PENR)	MJ	1.43E+11	1.49E+11	1.41E+11

	Use of primary non-renewable energy (PENR)	MJ	1.60E+05	1.59E+05
	Cumulative Energy Demand indicator (CED)	J/year	3.70E+05	3.69E+05

4. Conclusions

The study tested selected *cross-sectional* indicators of the Dashboard of Circular Indicators in the agri-food sector. The results highlight the importance of having a versatile tool that can systematize indicators by the level of application: Scope, Spatial Dimension, and Area of Sustainability.

The test in the Energy Scope allows us to interpret the energy data of the sector to be able to strategically address the future challenges of the ecological transition. The analyses, as well as highlighting the potential of this tool, have highlighted the national and regional imbalances that may arise from a biased reading of the data or a lack of secondary data (and discontinuous collection practices) in the Scope analyzed.

The complexity of the agri-food supply chain clashes with the difficulty of finding data at the regional level, where different collection systems do not allow an immediate comparison of results. The harmonization of energy-related data management systems, between national and regional data, can contribute to an immediate comparison, facilitating policy interventions aimed at correcting distortions in the production system or the market in general. Linked to these aspects is the difficulty of calculating certain indicators that do not make these tools accessible and user-friendly to all potential users. Hence the need, in line with the declarations of the European Commission, to have simple indicators that can express the degree of circularity, both at the macro and micro level (Stefano Poponi et al., 2022).

Analysis at the micro level is complex by the extent of detection over time (and the relative discontinuity in measurement). The testing of the indicators revealed the need to define structured systems for the internal monitoring of these data and to develop new *cross-sectional* indicators that can also consider the economic and social area as well as the product life cycle.

The indicators used showed a differentiated capacity for application concerning the different areas considered, revealing limitations in their application. The main criticality in their application occurs at the Macro level (Nation and Region) when considering the entire agri-food chain (agriculture and food industries). For the PER, PENR, and PE indicators, this criticality can be overcome at the national level, but not at the regional level. The different systems of data management and collection, as well as the timing of collection, make it complex to compare results, especially over a short time horizon. To overcome this critical issue, it is necessary to intervene in the harmonization of national and regional collection methodologies, building automatic mechanisms that can permanently and regularly monitor the trend of these energy indices.

A further critical issue is the calculation of the CED indicator at the Macro level. This is mainly due to the lack of data on the use of machinery or the presence of data that are too old, as evidenced in the literature by Ghisellini, Setti, & Ulgiati (2016). At the Micro level, this criticality is overcome by the direct collection of primary data and the use of software that facilitates its calculation.

The *cross-sectional* indicators of Scope Energy are only applicable to the area of environmental sustainability (Table 1). This entails a partial representation of Scope concerning the other areas of sustainability and implies the definition of new indicators to facilitate the measurement of circularity while also considering economic and social aspects.

At the research level, the main implications are related to the need to develop new indicators that can contribute to filling the gaps in the dashboard, especially the economic and social areas, which are the least investigated in the literature. The literature (see e.g. Corona et al., 2019; Moraga et al., 2019; Pauliuk, 2018) emphasizes the centrality of indicators with a life-cycle approach as a benchmark for evaluating circular practices. Indeed, the complexity of the value chain requires advanced analysis tools, including a life-cycle approach to assessing impacts within the three areas of sustainability (De Luca, Falcone, Iofrida, Stillitano, & Strano, 2015). The development of new indicators in this Scope must consider in addition to the *cross-sectional* characteristic the ability of the indicator to be used with a life-cycle approach.

At the managerial level, the use of indicators is the stimulus to adopt new circular business models. Monitoring the various Scopes allows for investment in critical points and increases the circular performance of companies.

At the policy level, the dashboard indicators can guide circular economy strategies in the agri-food sector through the coordinated use of several indicators, belonging to the different Scopes, for the redefinition of a more sustainable supply chain model.

The main limits of the work derive from the exploratory nature of the study, which considered a limited number of cases in this first test phase. Future steps will be aimed at broader comparisons within the same Spatial Dimensions or Sustainability Area, extending the analyses to international comparisons. This allows to test further the potential of the Dashboard and define the interconnection criteria between the indicators to assess the circularity of businesses in the agri-food sector. A further research step is to develop new indicators reflecting the above-mentioned characteristics, i.e. *cross-sectional* and life cycle. The last aspect of the research will be to promote the scalability of the model to further economic sectors.

Closing the Loop in the Agri-food

A review of best practices of waste management in the wine sector

Abstract

The transition from a linear economic system to a circular one is considered today as an inevitable change to guarantee a sustainable future for the next generations. However, achieving this goal requires considerable effort in reconsidering all stages of the value chain according to a closed-loop approach which ultimately allows for the reintroduction of waste material into the production process. From this point of view, among the industrial sectors, the agri-food is the one in which waste management could lead to important results. Indeed, the production of waste in this sector is one of the major problems in all phases of the life cycle of food, causing very high economic, social, and environmental costs. For this reason, and especially in recent years, the practices for the sustainable management of waste in the agri-food sector have become of great interest, which in a transdisciplinary perspective make it possible to obtain "zero waste" agri-food production. In this sense, the research focus on the opportunities that come from the wine sector. Through an extensive literature review, the authors provide a mapping of the best waste management practices currently used along the different stages of the wine supply chain, categorizing them through the concept of Circular Economy.

Keywords: Circular Economy, Agri-food, Sustainability, Recycle, Waste Management

1. Introduction

Traditionally, the economy is based on a linear model, which can be summarised by the formula: extract, produce, use, dispose (Ferrara, 2018). Although this model has been for decades at the heart of industrial development and has generated an unprecedented level of growth (Ellen MacArthur Foundation, 2015), on the other hand, it has produced devastating environmental and social consequences. The rapid depletion of natural capital resources is a clear example. The latest estimates show that the global use of materials

extracted and used for production has almost quadrupled in the last 50 years, reaching 100 billion tonnes in 2019 (Circularity Gap Report, 2022).

The possible alternative to this unsustainable development is known from a while as the “circular economy” (CE). This concept refers to an economy designed to be regenerative, where goods at the end of their life cycle are transformed from 'waste' into new 'resources'. In this context, materials reintroduced into the economy are referred to as “second raw materials”. These by-products can add value to production systems, nourishing the economy always with new lymph. In this sense, the circular economy is a new paradigm that, closing the loops in industrial ecosystems and minimizing waste (Stahel, 2016), changes the logic and geometry of the traditional economy, shaping it from a linear to a closed-loop system.

The implementation of the circular economy as a model of production and consumption is particularly important in the agri-food sector. In fact, the agri-food sector alone produces a significant amount of pollution. According to the Intergovernmental Panel on Climate Change (IPCC), considering all the stages of the agri-food supply chain, estimated that the entire sector generates between 21 and 37% of total global pollutant emissions (IPCC, 2019). The most impactful activities in the supply chain come from the agricultural phase, land-use change, and the loss and waste of food throughout the life cycle of products. The production of waste in this sector is one of the biggest problems in all phases of the food life cycle. According to FAO, lost or wasted food amounts to 1.3 billion tons per year (FAO, 2011). In particular, about 14% of the produced food goes lost between harvest and retail, while 17% of global food production is wasted and thrown away at the final consumption stage (FAO, 2022). This loss of value causes very high economic, social and environmental costs. These costs would be avoidable through careful waste management, that consequently could generate fewer polluting emissions.

Moreover, the agri-food sector has experienced the effects of climate change due to pollution, loss of biodiversity, and water scarcity. One example is the decrease in agricultural yields: since 1970, despite improvements in technology and farming techniques, the increase in productivity of cereal crops has decreased by 66% (Mark Esposito and Soufani, 2015). Therefore, if we want to ensure the availability of safe and healthy food for the 9 billion people estimated by the FAO by 2050, we need to change current production and consumption patterns and make them more sustainable (FAO, 2018).

In this respect, the circular economy could yield a win-win situation guaranteeing food security today and, in the future, and moderating the environmental impacts of the sector by proposing actions and solutions to readmit waste and by-products into the supply chain (Chiaraluce et al, 2021).

Among the various food supply chains, the paper examines the wine sector. This industry occupies a prominent role in the agriculture and agro-industrial sectors around the globe (Ahmad B. et all, 2020).

According to the International Organization of Vine and Wine (OIV), excluding juices and musts, the world wine production in 2020 was estimated at 262 mhl, marking an increase of almost 4 mhl (+2%), compared to 2019 (OIV, 2021). Grapes are one of the most important fruit crops cultivated worldwide, and the residue generated form wineries are among the major cause for environmental deterioration (Musee, N. et all, 2007). On the other side, the waste produced can lead to a big opportunity thanks to the organoleptic properties of the waste produced in this industry. If correctly studied, considering all the phases of the supply chain, it is possible to re-think a "zero-waste wine supply chain". Moreover, considering an increasing demand from the final customer for wines produced organically and with green production processes, this sector has become increasingly interested in sustainability over the years (Moggi et all, 2020). The proof lies in the growing number of environmental labels and sustainable programs for the implementation of environmental-friendly practices by winemakers. Following this increasingly green trend, the paper intends to provide the first analysis of waste management from the CE perspective in this sector. Through a comprehensive approach, the authors searched in the literature the waste management practices currently used in this sector and categorized them into CE practices along the main stages of the wine supply chain.

2. Methods

As a strategy to support a sustainable development and circular economy conceptualization and development, the research tries to figure out how to implement principles of circular economy in the agri-food sector, particularly in the wine supply-chain. The objective of this paper is double: on the one hand, it seeks to contribute to the literature on circular agri-food, which is still developing a shared and common definition and practices, on the other hand, it seeks to be a useful and practical tool for the various stakeholders in the sector, who want to improve their environmental performance. The paper focus on how the circular economy can be applied to waste reduction along the stages of the wine supply chain. Starting from the European Union directive on the waste hierarchy (Directive 2008/98/CE), the authors produced a double entry table (Table 1). The phases of the wine supply chain have been inserted in the columns, while in the rows of the table have included the waste management practices of the circular economy. Each supply chain depends on the waste materials generated and may adopt different practices to deal with the waste, giving it new value as a resource within the same supply chain, or being cross-used in others. For this reason, the waste management framework had been divided into five different phases in order of priority: Waste Prevention, Reuse, Recycling, Industrial symbiosis, and Recovery of energy. Finally, the practices have been classified according to the stage of the supply chain and the CE practices to which they belong. Research on waste management practices was conducted through a timely review of the scientific and grey literature. The authors consulted three scientific databases Google Scholar, Scopus, and Research Gate for the scientific articles, while the grey literature was selected by research institutes. In this sense, the main source used is the ENEA Report "Uso

efficiente delle risorse vitivinicole", where the wine supply chain was analysed to identify the key elements for resource efficiency. The literature review was performed via keywords. These keywords are: “Circular Economy AND Wine”, “Waste Management AND Wine Sector”, “Circular Economy AND Wine Sector”, “Waste Management AND Viticulture”, and “Circular Economy AND Wine Production”.

The sources of waste management practices have been highlighted in the table by an identification number. For completeness, an "Annex 1" with all the consulted numbered sources has been attached at the end of the text.

3. Results and Discussion

The research seeks to understand whether the adoption of CE practices applied along the wine supply chain can lead to zero-waste production. To do so, the authors found waste management practices in the literature. Subsequently, the practices were separated following the stages of viticulture, production, packaging, and consumption of the wine supply chain. Finally, waste management practices have been classified according to an order of priority dictated by the highest added value obtainable according to CE practices. Table 1 below summarizes the results of the research.

Table 1. *Waste Management Framework for the wine sector*

	Viticulture	**Wine Production**	**Packaging**	**Consumption**
Waste Prevention	Precision Viticulture (1,20); Efficient pruning (1).	System washing only when necessary (1); Promoting employee awareness of water saving (1). Water fooprint (1)	Limit the volume of materials used for packaging (1,9,11). Use compostable material. Use packaging from renewable raw materials (1,11). Bag in box (1);	Awareness, Responsibility in consumption to avoid waste during use (1,14). Environmental labeling and packaging certifications (16)

Reuse	Use of wastewater for fertigation if compliant with legislation (1). Foliar fertilization (1)	Reuse the water from the cellar washing to clean the floors (1); Reuse the water coming from the bottling line for different uses (1); Reuse wastewater to test the tightness of wine barrels (1) Reuse of purified wastewater for irrigation, civil and industrial uses (1).	Recovery of labels for reuse on other bottles (1); Bottle reuse (1).	Creative reuse of glass bottles (8) Returnable glass bottle.
Recycle	Chopping of vine shoots in the field as fertilizers/soil improvers (1); Burial of crop residues together with manure in the surface layers of the soil (1, 3) and possibly enriched with mineral elements such as phosphorus and iron as fertilizers/amendments (1).	Direct spreading on land for agronomic use (direct agronomic use) of grape pomaces (1,21); Composting (indirect agronomic use) of grape pomaces (1, 21). Allocate the wastewater with the highest polluting load to anaerobic digestion plants to produce digestate to be reused as a soil improver in agriculture (1).	Separate waste collection of packaging (paper, glass, and plastic) (1,15).	Separate waste collection of packaging (paper, glass, and plastic) (15).
Industrial symbiosis	Use of leaves for food purposes (1); Recovery and characterization of grape leaves by extraction of bioactive compounds (1); Pelletization of biomass (1, 4, 5,17).	Use of grape pomaces in Distillery to produce food (grappa), alcohol for industry (1); Use of grape pomaces in biorefineries for Food industry for grape seed oil (19); and Zootechnical industry, in the preparation of feed (1, 12, 21); Use of grape pomaces in biorefineries to produce components in Pharmaceutical, cosmetic, chemical, packaging industry (1, 12, 21);	Use of glass sand for the ceramics and cement industry (10)	

Energy Recovery	Energy production from vine wood of heat (1,2,18); Energy production from vine wood of gas oil (1,2,18).	Anaerobic digestion plants for wastewater with higher polluting load for biogas production (1) Recovery, quantification and gasification of pruning vine shoots / grape pomace for energy purposes (biogas, thermic energy, biofuels) (6, 7); Use of grape pomaces in Distillery to produce bioethanol for transport (1,22).		

Legend: In annex 1 we provided the list of cited papers used to classify waste management practices in the sector. **Source:** Authors' elaboration based on literature review.

Viticulture

In the agricultural phase, the main crop residue are the leaves and vine shoots removed during winter pruning (Novello, 2015). These wastes, to date, do not have a well-defined disposal chain (Pedrazzi S. & Allesina G., 2020). However, these residues, if reused, can generate added value for businesses.

Waste prevention. In the scientific literature analysed, several practices are present to prevent and limit waste production in the agricultural phase. The first technique is related to the efficient pruning of plants. Pruning is considered the key practice for regulating vegetative-productive development and controlling production in terms of quantity and quality (Sposato et. al, 2018). In addition to stimulating plant productivity, it prevents the onset of diseases and thus safeguards the plant from pathogenic elements (Colapietra, M. et al, 2002). Together with the techniques of precision viticulture, which guarantee knowledge of the state, health, vigour, and physiological needs of the vines in specific areas of the vineyard, they make it possible to adapt cultivation techniques precisely to the needs of the plants. In this way, grape production is more sustainable, safe, and with fewer pruning residues to dispose of

Reuse. According to the scientific literature, two practices have been found for reusing agricultural residues from the agricultural phase: the first concerns the use of foliage as fertilizer (Sposato et. al, 2018). Plants can absorb nutrients through their leaves (Lalatta F., 1957). This method allows for to integrate and correction of some mineral deficiencies (such as calcium salts, magnesium, or boron deficiency). A further fertilization technique is obtained thanks to the reuse of wastewater from cellars (Sposato et. al, 2018). It is possible to reuse wastewater for agronomic purposes by spreading it into the ground, within the limits imposed by law

(Legislative Decree 152/2006).

Recycle. The techniques for recycling the pruning are different. The shoots rich in organic and nutritional substances are fundamental for the good and lasting fertility of the soil (Meglioraldi et all, 2007). In this sense, the recycling practices that concern them are different. First of all, it is possible to cut the vine shoots directly in the field. This practice can return a certain amount of humus to the soil annually, saving on fertilizers and management costs (Sposato et. al, 2018). Another technique for the recycling of pruning residues consists in using the wood chips in layers with the manure in heaps greater than 150 and left to ferment for 3-5 months (Meglioraldi et al, 2007). The generator fertilizer can also be enriched with additional mineral elements (phosphorus and iron).

Industrial symbiosis. In this phase of the supply chain, results from the literature review highlights two possible practices to be classified as "industrial symbiosis". The first concerns the use of grape leaves in the food industry (Sposato et. al, 2018). Grape leaves are used as a culinary ingredient in the kitchens of different countries (such as Italy, Greece, and Romania). The second opportunity is given by the vine shoots, which once placed in bales, and left to naturally dry in the air, are then ground for the production of pellets (Pedrazzi S. & Allesina G., 2020). In particular, the agripellets produced with raw materials with lower ash content, such as for vine pruning, have characteristics very similar to wood chips. This aspect promises an interesting potential for use as an alternative or reserve fuel in district heating systems, in rural users, or in industrial boilers (Toscano, 2013).

Energy recovery. The alternative and final use of vine shoots is their use of energy as biomass. According to Novello, pruning residues can amount to a few tons per hectare (Novello, 2015). With
4.25 kg of vine shoots, the heat generated by 1 kg of diesel is generated, while the gasification of the vine shoots can lead to yields of around 4.25 kW / ha (Corradi, 2006). This type of use of the residue generates a series of economic and environmental advantages. The pruning residues can be arranged in bales by the farm. If the bales are small, through special boilers inside the company, they can be transformed into energy, giving the farm greater energy autonomy. Conversely, if the bales are large, the vine shoots must first be chipped. For this reason, the biomass is sold outside (consortia). In this way, diversification of income sources and a general increase in employment is generated for the farmer (Sposato et. al, 2018). Furthermore, this practice guarantees an environmental gain in terms of pollution reduction.

Wine Production

During the wine production phase, the waste is mostly of two types: the residues deriving from the processing of the fruit and the wastewater deriving from washing the equipment. The former is essentially composed of the stalks obtained after pressing the grapes, the pomace resulting from the pressing phase, the lees obtained

following fermentation, and the filtration residues resulting from the clarification process (Bioactive-net, 2008). The volume of solid waste produced during the vinification phase represents approximately 20% of dry matter of the harvested grapes (Da Porto C., 2013). In this sense, the valorization of these residues is extremely important as it allows to obtain economic and environmental advantages (Sposato et. al, 2018).

Waste prevention. The actions to prevent the production of waste found in the scientific literature essentially concern the minimization of water consumption and the consequent lower production of wastewater. In this case, it is possible to act on multiple factors. First, it is possible to promote greater awareness of the importance of saving water resources for employees, directly acting on the prevention of wrong behavior (Sposato et. al, 2018). Secondly, good practices can be implemented directly on equipment and process lines. Examples concern the washing of the systems when exclusively necessary or the alternation of water jets with compressed air for washing the equipment. The latter practice involves a 50-75% reduction in water consumption compared to low-pressure systems (Sposato et. al, 2018). Thirdly, use the water footprint to monitor direct and indirect water consumption linked to the consumption of fresh water in the vineyard and the wine production process (Sposato et. al, 2018).

Reuse. The reuse practices related to the wine production phase mainly concern, also, in this case, the water resource. In fact, according to Aeneas, it is possible to reuse water:

- washing the cellar for cleaning the floors;
- washing in the bottling line through special by-passes, and reusing it in the same processor for cleaning tanks or tankers, or, for cleaning floors or irrigating fields;
- of wastewater to test the tightness of the barrels.

Recovering wastewater and reusing it in these different ways allowed, in addition to saving water consumption, to avoid its mixing with another wastewater. This could create difficulties in purification plants or reduce the potential for energy production (Sposato et. al, 2018).

Furthermore, wastewater, after having been purified (Decree 185/2003, Legislative Decree 152/2006), can be used for irrigation, civil and industrial uses.

Recycle. The practices analysed in the literature concerning the possibilities of recycling of by-products and waste deriving from the winemaking process within the same company concern the possibilities of spreading on the land, and their indirect use in agriculture from their composting and subsequent use as fertilizer. According to the literature, it is also possible to reuse wastewater with a higher polluting load as digestate to be used as a soil improver in agricultural fields (Sposato et. al, 2018). This practice takes place by sending the wastewater to anaerobic digestion plants, were once treated, they enhance the production residue by decreasing the environmental impact and the production of waste.

Industrial Symbiosis. The residues deriving from the vinification phase can be considered as by- products with high added value. They represent a considerable source of organic matter, polyphenols, nitrogen, and micro and macro elements. In particular, by processing the product in biorefineries it is possible to transform the biomass of production residues into a range of bio-products that can be used as raw material for various industries (Da Porto C., 2013):

- Food, Pharmaceutical, and Cosmetic. These industries can exploit bioactive compounds (nutrients, antioxidants, and antimicrobials) in their productions (Sposato et. al, 2018). These components are the raw material of other industries, an example concerns the production of food supplements (Da Porto, 2013), or the production of dyes through grape skins (Sposato et. al, 2018).
- Animal husbandry. The pomace, together with grape skins, can act as supplements/additives for animal feed (Sposato et. al, 2018).
- Chemistry, Biomedical, and Packaging. These industries can exploit the great opportunity derived from biopolymers (Da Porto C., 2013). An example concerns the production of Bioplastics to produce packaging (Da Porto C., 2013).

Sold individually in the distillery, the pomace and lees become the raw material to produce grappa, alcohol for food and industrial use, but also the production of bioethanol, dyes, and grape seed oil (Sposato et. al, 2018). This destination represents a double economic advantage for the agricultural entrepreneur. On the one hand, it is a source of income. Novello estimates an average price of 2.2 euros per quintal of marc and 4.5 euros per quintal of lees. On the other hand, sending production residues to the distillery represents an avoided cost related to waste disposal (Novello V., 2015).

Energy Recovery. The literature recognizes the fundamental role of waste deriving from the second phase of the wine production chain in the production of energy. The practices analysed are different and it is possible to recover all production residues. Biomass is a renewable energy source; therefore it gives rise to clean energies. First, the pomace can be used as a substrate for anaerobic digestion to produce biogas (Sposato et. al, 2018). Furthermore, the pomace can be further recovered after distillation and dried in pellets to produce heat and co-generation (Sposato et. al, 2018). Likewise, lees can be used for energy purposes to produce biogas together with other materials (Da Ros et all., 2014). It is also possible to recover energy even from wastewater with a higher pollutant load. They can be destined for anaerobic digestion plants to produce biogas (Sposato et. al, 2018).

Packaging

The waste produced in the third phase of the wine supply chain relates to the materials used in the packaging for the distribution and consumption of wine. Among these materials, we find glass, paper, Tetrapak, plastic,

cork, and aluminium.

Waste prevention. Wineries can use various practices to prevent the production of waste in the packaging phase. First, it is possible to limit the volume of materials used for packaging. In this sense, it could be useful to reduce the weight of the glass bottles or to replace the bottles with the Tetra Pak. Tetra Pak packaging is lighter than glass, which generates additional benefits such as lower product shipping cost, and thanks to the flexibility of the packaging, it is less likely to break, reducing product loss and damage. induced by the rupture (Thompson-Witrick A. et all, 2021).

A further practice to be implemented to favour the reduction of the quantity of waste related to packaging is the sale of bulk wine (or bag in box wine). The packaging of wine has continued to evolve over the years and the sale of wine, and the bag-in-box can be counted among the most significant changes in the distribution and sale of the product. Bag-in-box packages consist of a bag of plastic material enclosed in a rigid box (Thompson-Witrick A. et all, 2021). This practice allows to reduce the number of materials used for storage (Sposato et. al, 2018) and reduces packaging for the consumer to zero. According to the report "Bag-in-Box Market" published by Markets and Markets, the bag in box market is s projected to grow from USD 1.6 billion in 2019 to USD 1.9 billion by 2024, at a CAGR of 3.8%. So, also the industry would benefit of this growing trend.

Reuse. The practices concerning the reuse of packaging within the company are related to the recovery of empty bottles and the recovery of labels for reuse on other bottles (Sposato et. al, 2018). These practices make it possible to limit the number of raw materials to be purchased for the production of wine and also reduce the quantity of waste produced and therefore the related costs for their disposal.

Recycle. The best recycling practice for packaging is a separate collection. In addition, two of the materials present in the packaging, glass, and aluminium, can be infinitely recycled, bringing waste materials to new life.

Industrial Symbiosis. An example of industrial symbiosis comes from glass recycling. Glass treatment plants give rise to types of waste that appear in the form of sludge and dust containing large quantities of glass. The industries that use these wastes as raw materials for their productions are the ceramic materials industries, and the cement and road substrates industries.

Consumption

The last phase of the supply chain analysed from the place exclusively to the waste deriving from the packaging of the wine.

Waste prevention. The packaging is labelled such as to contain for consumption to read the instructions to facilitate the delivery of differentiated waste and recycling of organic waste. The environmental labels shown on the pack play an interesting role in talking to the consumer about the characteristics of the product and of the pack itself (Conai, 2021). Raising awareness among citizens and businesses is very important to obtain better results and spread the culture of recycling, to facilitate the transition to the new production model and the circular economy.

Reuse. The re-use activities adopted to date are limited to the possibility for consumers to practice the vacuum to return directly with companies. This practice favours a win-win situation, both for the consumer and for the producer. For the consumer, there is an economic saving, while for the producer a cost is avoided in the acquisition of the packaging necessary for the distribution of wine. Furthermore, in the literature, there are also practices of creative reuse of packaging by consumers. Once consumed, the packaging can take on a new life by acquiring added value (upcycling), for example in terms of aesthetic value for the person who reuses it (Wilson, 2016).

Recycle. The best practice for recycling products related to the wine sector is the separate collection. This practice makes it possible to adopt the waste in a differentiated way to the collection and recovery centers. In this way, the recycling of discarded materials is optimized.

4. Conclusions

The current context of resource scarcity, global climate change, environmental degradation, and rising food demand are major problems in our present and the future. In this sense, the circular economy represents a promising strategy to support sustainable, resilient, restorative, and regenerative agriculture.

Agriculture is one of the sectors in which it is easier to close the cycle of resources used for production. The great opportunities that derive from the various agri-food chains lie in its natural ability to produce a series of transversal by-products in different sectors: from the agri-food sector itself to the textile, cosmetic, pharmaceutical sector or, finally, many of these residues have the potential to become energy, as happens in biorefineries. This happens in the wine industry. Indeed, following the grape processing to obtain wine, a series of by-products and waste can be transformed into valuable products.

However, applying the circular economy means rethinking all the phases of the supply chain in a more sustainable way and researching and applying all the practices for managing the waste produced. This paper, following all the stages of the wine supply chain, has highlighted the best waste management practices, trying

to categorize them within the circular economy processes.

The results showed how the wine sector can be considered as a zero-waste industry. If correctly applied, waste management practices can not only reduce pollution and the impact on resource depletion, but also bring economic gains for companies in the sector.

Information Challenges in a Circular Economy

An empirical investigation of the availability and quality of sustainability-related data in the manufacturing sector

Magdalena Rusch, Josef-Peter Schöggl, Rupert J. Baumgartner

Christian Doppler Laboratory for Sustainable Product Management enabling a Circular Economy, Institute of Systems Sciences, Innovation and Sustainability Research, University of Graz, Merangasse 18, 8010 Graz, Austria, magdalena.rusch@uni-graz.at

Abstract

To move from a linear to a circular economy, stakeholders along the value chain need sustainability-related data, e.g., about the composition of products and their state of health, from the entire product life cycle, and preferably in digital form. Manufacturing companies play a vital role in collecting and sharing data along the supply chain (in an automated way), enabling more transparent product life cycles and getting closer to creating so-called digital product passports. Furthermore, these sustainability-related data are essential for sustainability assessments and product compliance, i.e., fulfillment of product-related laws. However, data management along the product life cycle is challenging for several reasons, e.g., it requires a lot of time to collect data, and the willingness to share data is lacking. This study shows what sustainability-related data is already available, in what quality it is available, and what problems companies encounter when acquiring or using it. Our results demonstrate which kind of (high-quality) data is there in manufacturing companies and what challenges they face regarding collecting and using data internally and from their suppliers. Also, the advancing digitalization to find ways to ease the identified challenges is part of the discussion. The results could be the starting point for further research on how certain information challenges in a circular economy could be dissolved.

Keywords: Smart Circular Economy, Sustainability, Data Management, Digitalization, Survey

1. Introduction

The current way of extracting and processing primary resources cause around half of the total greenhouse gas emissions released and more than 90% of the biodiversity loss on the planet (IRP, 2019). How companies

create value and do business is an important factor and source of emissions and waste (Whiteman, Walker, & Perego, 2013). A promising approach for advancing the sustainability of value chains and value creation is the concept of a circular economy or circular economy business model where the consumption of (virgin) resources and the generation of waste is decreased by slowing, narrowing or closing resource loops (Bocken, de Pauw, Bakker, & van der Grinten, 2016; EMF, 2015).

One critical part of enabling a transition towards a more sustainable and circular economy is (consistent) data flows along the value chains (Luoma, Toppinen, & Penttinen, 2021). Data can be defined as elementary symbols that are based on the observation of events or objects (Rowley, 2007). Data needs contextualization to bring value or direct usability (Kristoffersen, Blomsma, Mikalef, & Li, 2020). For assessing and improving the sustainability performance of products, sustainability-related data about the product, its parts, or materials must be shared in a structured way with various stakeholders, from manufacturers, importers, and distributors to repairers, remanufacturers, and recyclers (European Commission, 2022). Also, the consumers should be able to make informed decisions about the product, e.g., increased transparency enables them to choose more sustainable products (European Commission, 2020). As soon as data is transformed by using techniques such as sorting, selection, aggregation, or interpretation, it becomes information (Kristoffersen et al., 2020; Rowley, 2007). For example, at the design phase, data about product characteristics and disassembly procedures are gathered, and by sharing it with different stakeholders along the value chain, it can be "transformed" into information that facilitates the repair of a product (Acerbi, Sassanelli, Terzi, & Taisch, 2021).

However, the current lack of sustainability-related data that are shared along the product lifecycle limits the ability to offer more sustainable products (European Commission, 2022). Sustainability-related data such as material composition, production processes, state of health, or transport distances are vital for sustainability assessments, e.g., Life Cycle Assessments (LCAs), to treat products in a sustainable manner and according to their intended purposes in a circular economy. For example, with increased and structured sustainability-related data, the product life can be prolonged by enabling predictive maintenance activities (European Commission, 2020). Thus, for manufacturing companies, sustainability-related data is essential for (data-driven) decision-making and process execution in a circular economy (Preut, Kopka, & Clausen, 2021). They depend on accurate, high-quality data from the entire product lifecycle to conduct LCAs and make informed decisions (Luoma et al., 2021). They need the product, material, and process data, hence data from their own activities and upstream and downstream stakeholders along the value chain. These data are not always available due to several problems regarding consistent data flows along a (circular) product life cycle. For example, other studies report a low willingness of the respective stakeholders to share data due to issues concerning the sensitivity or disclosure of data (Bressanelli, Adrodegari, Pigosso, & Parida, 2022), and if shared, it can be incomplete or incorrect (Grambow, Mundbrod, Kolb, & Reichert, 2015; Ingrao et al., 2021).

Different problems can also arise depending on the data source (e.g., internal or supplier data) or tasks that need to be done (e.g., data collection or utilization). Some companies have already implemented software solutions for data management tasks, and others collect the data in specific files (e.g., MS Excel) (Grambow et al., 2015). This implies that the variability of assessing (internal) data can be quite high and lead to large delays if the data is not yet available but must be gathered manually before sharing (ibid.). Although research on the importance of (real-time) data collection and sharing to enable a more sustainable and circular economy has received increased attention in the last few years (Fritz, Schöggl, Baumgartner, 2017; Ingrao et al., 2021; Luoma et al., 2021), research about the status quo of data availability and quality, in the manufacturing sector, remains scarce (Schöggl, Fritz, & Baumgartner, 2016). Therefore, the present study attempts to address the following research questions: 1) What data are available for companies' sustainable product management, and what is the quality of such data? And 2) What are the most common data acquisition and usage problems of companies?

This study aims to identify the status quo of the availability and quality of sustainability-related data in (manufacturing) companies and data collection as well as data utilization problems. The discussion section outlines the potential of digitalization advancements to ease information challenges, and further research issues are described.

2. Methods

Firstly, data acquisition and usage problems of sustainability-related data were compiled and analyzed from the literature. Secondly, a survey was used to examine the status quo of the data availability and quality as well as the most common acquisition and quality problems of sustainability-related data in companies. The telephone survey was conducted between February and December 2021. In total, 1549 manufacturing companies were contacted using a random sampling method. The survey was answered by 132 sustainability managers or CEOs from Austrian manufacturing companies which is a response rate of almost 9%. The survey questions can be found in Appendix A. In this survey, a 5-point Likert scale was used, ranging from "not available at all" to "fully available" for the data availability part and from "insufficient" to "very good" for the data quality part. The third part consisted of questions about the frequency of data acquisition and usage problems, and here the response options ranged from "never" to "always" (Table 1.).

Table 1. Scales development for the survey (full questionnaire see Appendix A).

Survey scales	Number of questions/items	Response options	Sources
Demographics	3		
Data availability	Internal: 6 Suppliers: 8 Use– and end-of-life phase: 3	1. not available at all, 2. scarcely available, 3. partly available, 4.largely available, fully available	(Schöggl et al., 2016) + own definition
Data quality	Internal: 6 Suppliers: 8 Use– and end-of-life phase: 3	1. insufficient quality, 2. low quality, 3. satisfactory quality, 4. good quality, 5. very good quality	(Schöggl et al., 2016) + own definition
Data acquisition and usage problems	Internal data collection: 5 Supplier data collection: 5 Data usage problems: 4 + open question about other data collection or management problems	1. never, 2. rarely, 3. sometimes, 4. oftentimes, 5. always	(Schöggl et al., 2016) + own definition

The data analysis and graphical depiction were done using descriptive statistical methods and the programs MS Excel and "R" (R Core Team, 2019). The sample characteristics are illustrated in Figure 1. Most companies belong to the machinery and metal goods industry, followed by companies from the chemical and food industries. Finally, companies with other industry affiliations than those shown in Figure 1a were summarized under the category "other" which includes companies that, e.g., focus on the production of sports equipment, furniture, printing equipment, or ceramics. Figure 1b and Figure 1c show that most companies in the sample are small companies with an annual turnover below 10 million euros and below 50 employees (46%). Middle-sized companies with 50-250 employees account for a share of 32%, and large companies with more than 250 employees account for 22%.

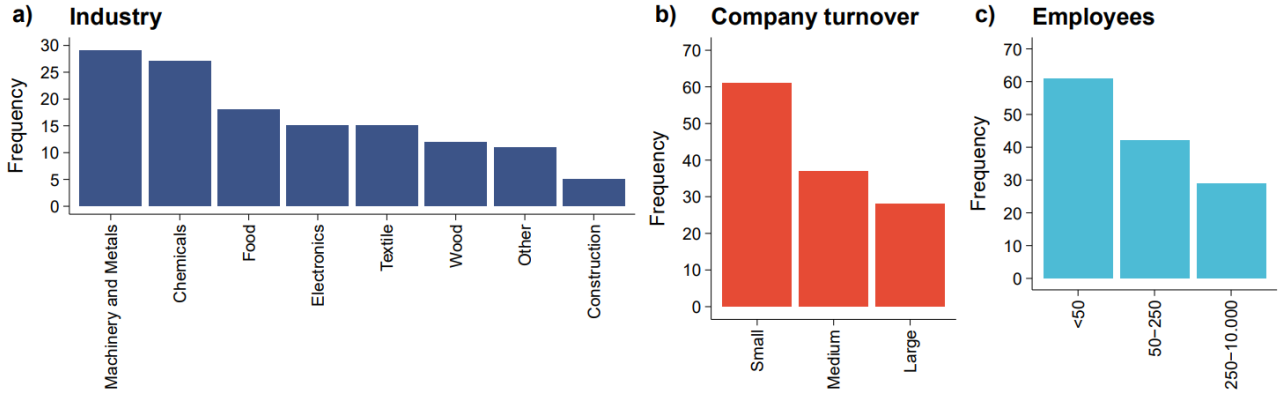

***Figure 1**. Characteristics of the companies in the sample. a) Distribution according to industry. b) Distribution according to company turnover. Small <= 10 Mio. Euros turnover, Medium <= 50 Mio. Euros turnover, Large > 50 Mio. Euros turnover. c) Distribution according to the number of employees.*

3. Results and Discussion

In our findings, the data sources were categorized into three areas: company-internal, supply chain, and the use- and end-of-life phase, to assess the data availability and quality. Additionally, questions about problems with the data acquisition (internally and from suppliers) and data utilization were included in the survey.

Company internal data availability and quality

As shown in Figure 2, the availability of data from internal company processes is considered already high in general and especially high for data about the total energy use (84% sum of all blue bars) and the waste generation (80%) of the companies. For the other three areas, at least 60% of the companies stated that data about the energy consumption per machine (65%), the recycling rate of the company (61%), and the total emissions (61%) are partly, largely, or fully available. The highest share of data that is not at all or only scarcely available is data about the companies' recycling rates (23%) and total emissions (22%). The highest percentage of answers about "missing knowledge" (colored in dark red) was reported when we asked about the companies' total emissions (n=23). An open question about other available data for sustainable product management showed that no other data was reported in almost all cases except in one case where a respondent from the electronics industry mentioned that the company has data available about the use of the building. Regarding the data quality, the results show that largely or fully available data are also there in very good quality (e.g., total energy use within the company). Data about waste generation is also there but less often of very good quality. Internal companies' data availability and quality are generally already high and good.

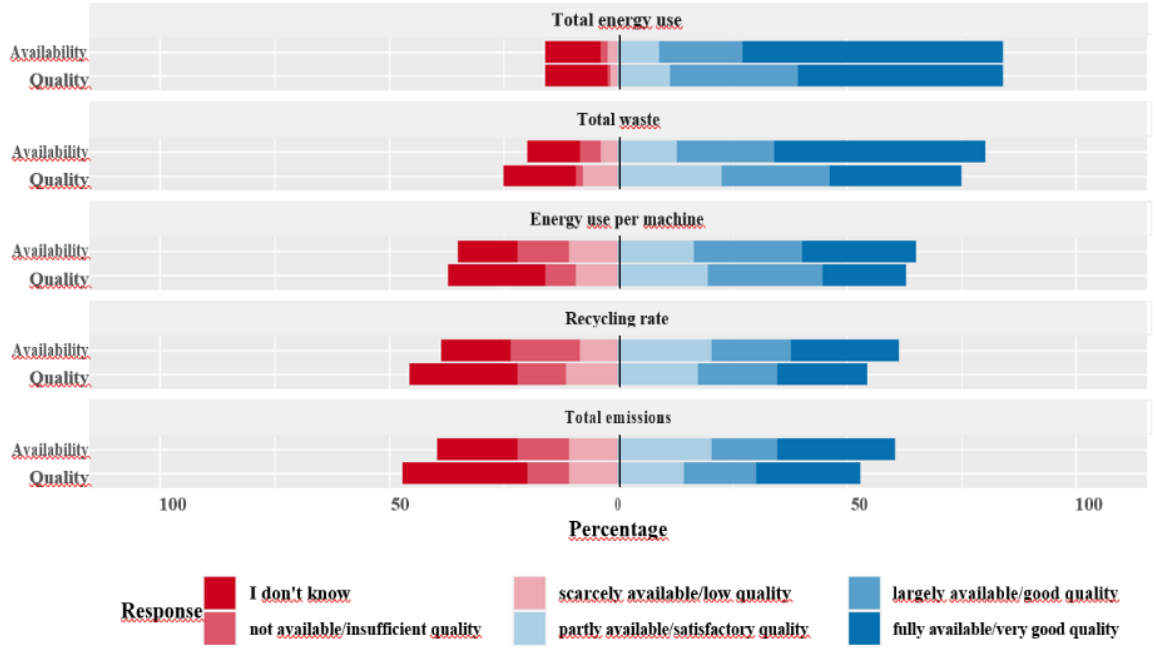

Figure 2. *Company internal data availability and data quality.*

Supply chain data availability and quality

Data from suppliers are primarily available for the material composition of products or parts of the product (79%, sum of all blue bars), and at the same time, the data are available in high quality (Figure 3). Interestingly, legally required data from regulations like registration, evaluation, authorization, and restriction of chemicals (REACH), restriction of hazardous substances (RoHs), or conflict minerals data are only available in 73%. However, a quite high number of companies (n=24) did not know if the data were available. This could mean that the regulations do not apply in their industry. Almost 69% of the companies have data available about the transport distances of their products and 67% about the production procedures employed in the supply chain, at least partially. The least data are available about the waste generated in the supply chain (46% are not at all available, and 0% are fully available). The data quality correlates positively with the data availability. The data quality is also the highest for the first four aspects with the best data availability. Respectively for the aspects: material composition of the product or its parts, compliance (legally required information), transport distances, and employed production procedures, the data availability and quality are high. The lowest data quality was reported to come from data about the waste generation and emissions within the supply chain, with 25% and 21% that say it is insufficient.

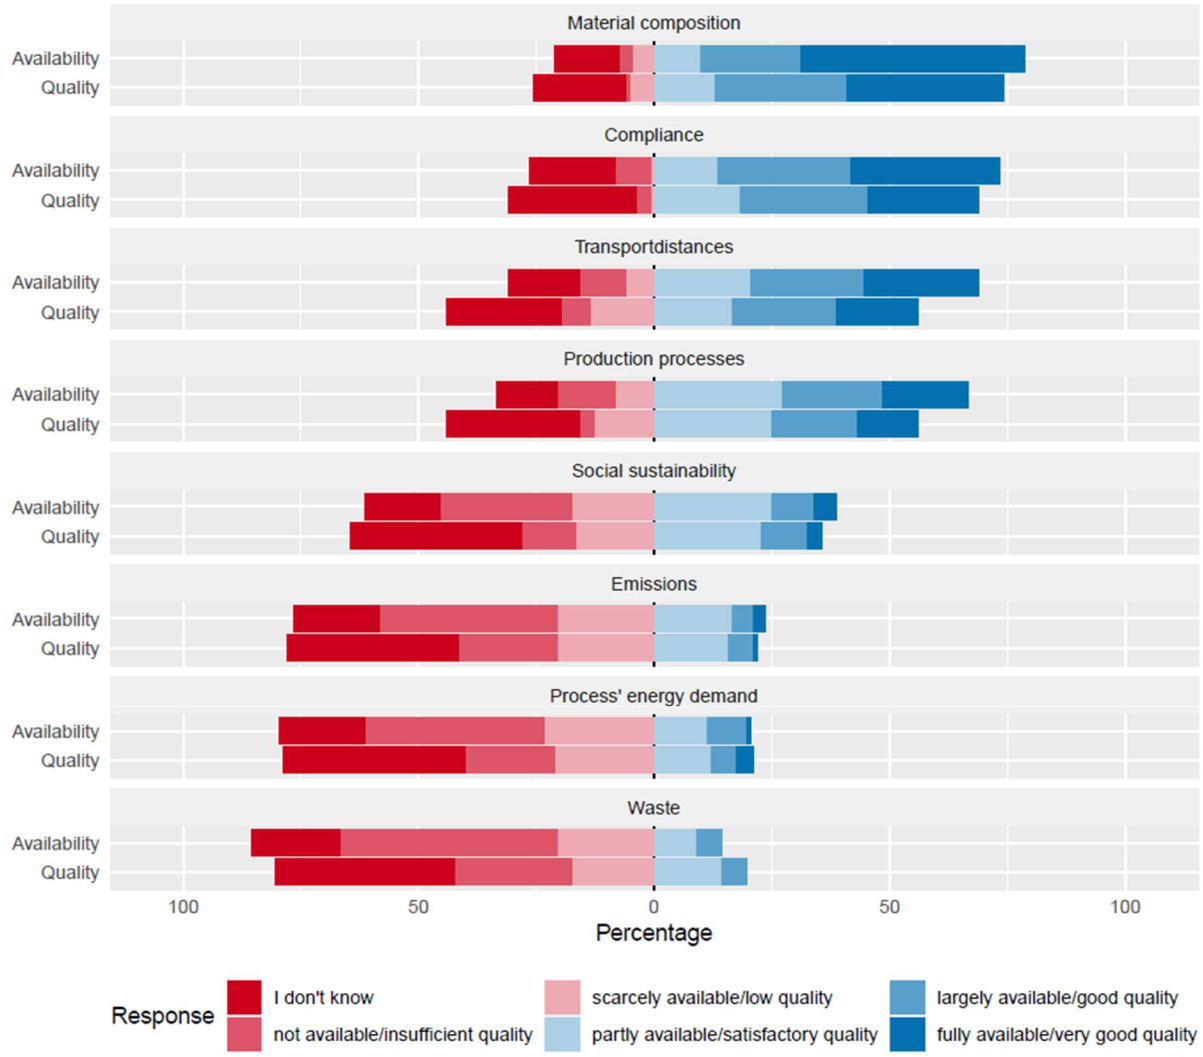

Figure 3. *Supply chain data availability and data quality.*

Use- and end-of-life phase data availability and quality

The companies were also asked about the data availability from their products' use- and end-of-life phases (Figure 4). Around 37% (sum of all blue three bars) of the companies in our sample have some data available about the energy demand during the use of the product but, in most cases, only partially. In 23% of the cases, such data is not available at all. Data about the end-of-life routes are available in 30%, and data about the recycling rates are available in 27% (sum of all three blue bars). However, the number of respondents who don't know if this data is available is the highest (n=36) for the latter aspect. The data quality is satisfying,

good, or very good in 33% for the energy demand in use, 29% for the end-of-life routes, and 23% for the recycling rates.

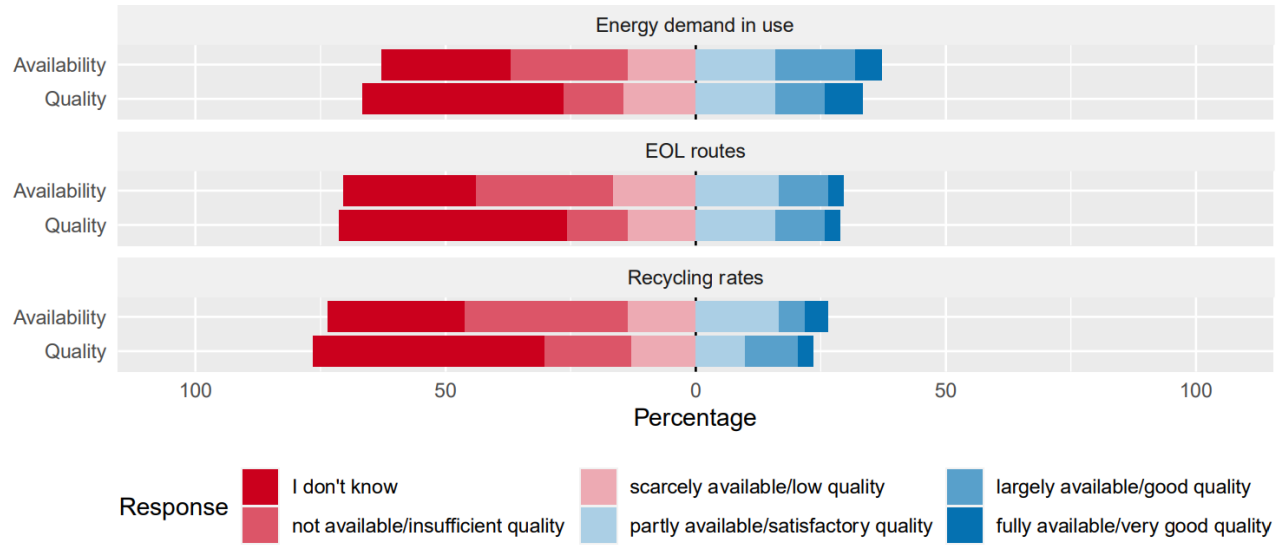

Figure 4. *Use- and end-of-life phase data availability and data quality. EOL = end-of-life*

Data acquisition and usage problems

The most common problem for internal data acquisition is the required time for collecting the data (56%, the sum of all blue bars in Figure 5a). Additionally, 39% reported problems with internal communication between persons/departments. Other problems are data collection costs (35%), missing data (33%), and the data's confidentiality is only an issue for 11%.

Analyzing the data acquisition problems in the supply chain (Figure 5b) showed that 48% have issues with suppliers' insufficient knowledge about sustainability topics. Also, incomplete data is a problem in 42% of the cases. Missing data, confidentiality, and incorrect data are a problem for 31%, 30%, and 28%, respectively. In almost all cases, these problems are "sometimes" the case, and respondents rarely said this is "always" the case.

The sustainability managers/CEOs were also asked about the most common data usage problems (Figure 5c). They ranged from the time required for data usage/analysis (56%), lack of sustainability expertise of employees (49%), and a variety of sustainability assessment methods (44%) to the least often mentioned problem about the cost of data use/analysis (38%). An open question was included to give the possibility to add any other issues that sustainability managers face when collecting and managing sustainability-related data. However, no additional problems were mentioned by the 132 respondents of the survey.

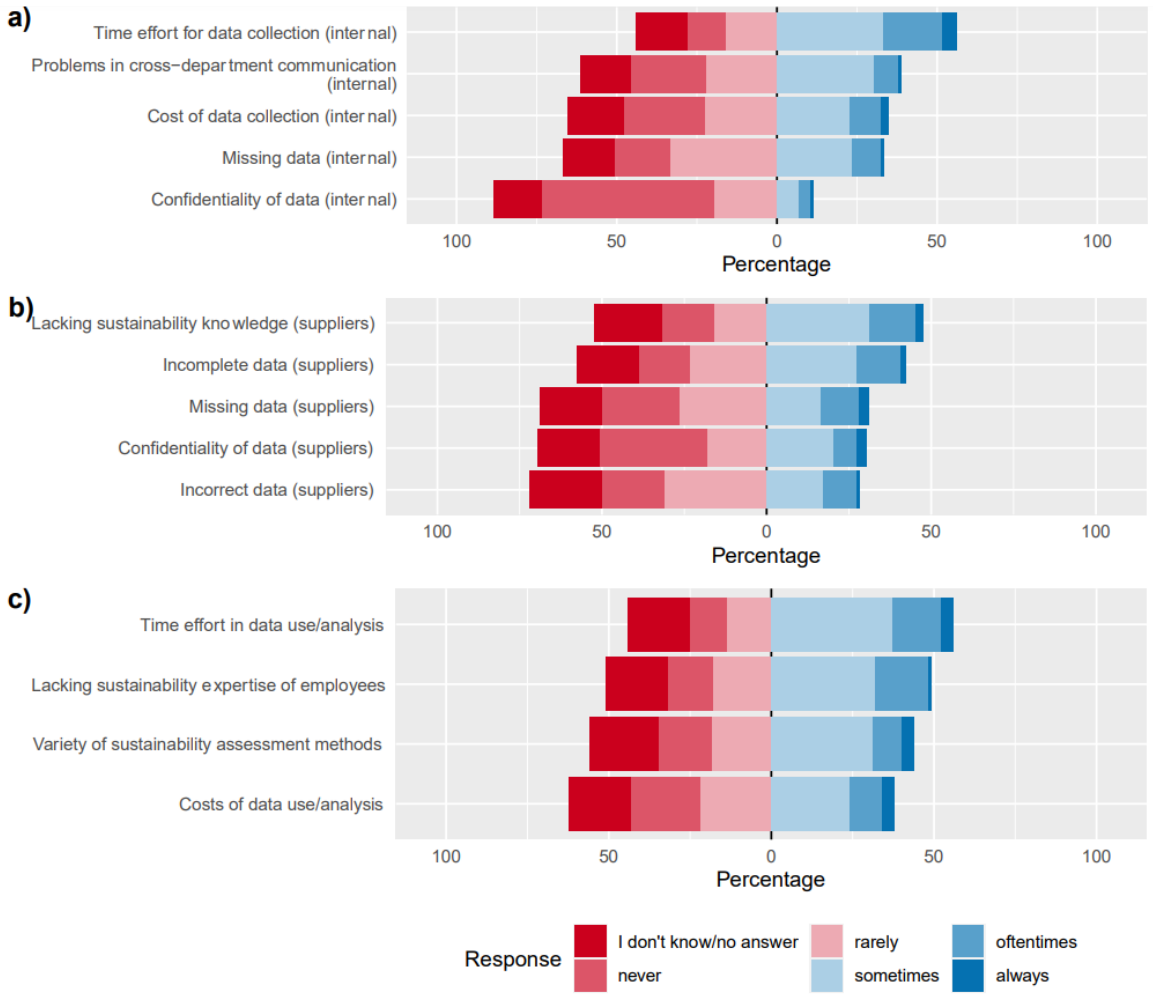

***Figure 5**. Data acquisition problems a) internally and b) from the supply chain. c) Data usage problems.*

4. Discussion

Most high-quality data are available from the companies' internal processes, e.g., energy consumption and waste generation. Even the energy consumption per machine, which is an important input for product LCAs, is already quite well known. However, there is a problem with internal data-sharing or cross-department communication. When we asked about data from suppliers, the availability becomes less, e.g., for the energy consumption of production processes or waste generation in the supply chain, and the suppliers' knowledge about sustainability topics is also lacking. Furthermore, very little data are available from product use- and end-of-life phases. Others also confirmed that the information flow often stops after the product is handed over to the user/customer (Preut et al., 2021). The lack of available data from stakeholders throughout the product lifecycle, including information about the materials used, design features, standards, or actual costs

of end-of-life treatment of products, makes it difficult for stakeholders to make informed decisions (Sachdeva, Araujo, & Hirschnitz-Garbers, 2021).

For example, at the end-of-life phase, stakeholders could treat products differently if they knew more about the materials used (for less complex products with limited parts) or the actual state of health of the product (for more complex products).

However, which data should be collected or how such data can be managed is not only an information technology (IT) oriented issue but a strategic (data management) question (Grover, Chiang, Liang, & Zhang, 2018). Before data are collected, a clear goal and purpose for why specific data are needed should be determined (Stryeck, Jean-Quartier, & Tschabuschnig, 2022). Otherwise, collecting, storing, and aggregating data that are never used could lead to high (economic and environmental) costs (ibid.). Unfortunately, when such a decision should be made, it is not always clear which data (type and format) will be useful in the future. This "data management/collection paradox" makes it even more challenging to decide early (e.g., in the product design or development phase) which data should be collected now or during the use phase of a product. For instance, it could be beneficial to gather information about how previous versions of a product were used and treated at their end of life to improve the current product design. By embedding sensors into new products and adding unique identifiers, data could be gathered to provide information for future design-for-circularity activities, and this could be passed on (digitally) to customers and end-of-life actors that can be helpful later to support the realization of different circular economy strategies.

As a starting point, a minimum requirement of data that needs to be shared along the value chain of products is defined in a proposal for the so-called "digital product passport" for various products in the European Union (EU) (European Commission, 2020). Structured information should be shared along the product lifecycle to help make informed and data-based decisions. For example, a product's sustainability impact or state of health could be assessed more easily with the means of a digital product passport and, at its end-of-life, it can help treat products in a circular economy according to their intended purposes (Lemos, 2020). Also, tracking the origin of a product and transparently storing and sharing information along the value chain by using blockchain technology for such a passport is discussed in the literature (Böckel, Nuzum, & Weissbrod, 2021; Saberi, Kouhizadeh, Sarkis, & Shen, 2019). Because of examples such as the latter, blockchain technology is described as a potential enabler to overcoming some information challenges in a circular economy.

Manufacturing companies will have to provide (sustainability-related) data to enable such a digital product passport. Therefore, they need a lot of data about their products and processes (e.g., it could become mandatory to report on the sustainability impact of a product). However, our assessment showed that companies often lack data, especially from the use- and end-of-life phase, as well as data from the supply chain (e.g., emission and waste data). And to derive valuable insights from these data, several dimensions of the data quality are

essential, e.g., completeness, timeliness, consistency, or accuracy (Grover et al., 2018). The quality of the supply chain data (e.g., about the waste generation, energy consumption, or emissions) is rather low in most cases of our sample. Here, the goal should be to define data quality standards to facilitate the data management of all stakeholders and enable the opportunity to use the collected data also for analytical tasks. Further research is needed on how the quality of sustainability-related data can be assessed and secured. For example, data science approaches could help enable automated plausibility checks of this data.

Among other things, the manufacturing companies also reported problems with the time required to collect data internally and incomplete data from suppliers. The advancing digitalization could facilitate collaborative action from the supply of raw materials to final disposal, allowing for a better analysis of environmental, social, and economic impacts (Siltori et al., 2021). The use of new digital technologies could facilitate the collection, management, and exchange of sustainability-related product data to further contribute to a circular economy (European Commission, 2020). For example, internet-of-things applications could help collect production or supply chain data (Gligoric et al., 2019). Tracking the origin of products is seen as a typical example of the use of blockchain technology (Böckel et al., 2021), and big data analytics has a considerable potential to support sustainability and circularity-related decision-making throughout a product's life cycle (Rusch, Schöggl, & Baumgartner, 2022). This could help manufacturing companies achieve their circular economy and sustainability goals by enabling the flow of materials and information (Di Maria, De Marchi, & Galeazzo, 2022). Nevertheless, good data availability and quality are only the starting point for generating valuable insights and knowledge for decision-making (Grover et al., 2018). Companies that want to reveal the value of data must also take care of skillful human resources and the right analytical tools (ibid.).

5. Conclusions

In this study, the availability and quality of sustainability-related data from the product life cycle and problems with the data collection and use were examined by conducting a survey with 132 sustainability managers from manufacturing companies. The results show that both the data availability and quality rank from high (internal data) to rather low (supply chain data) and low (use- and end-of-life phase). Thus, most companies still lack sustainability-related data, hence information about waste generation in the supply chain and the use- and end-of-life phase of their products and materials. However, to perform sustainability assessments like LCAs and for data-based decision-making in companies, high availability and high-quality data are necessary for a solid outcome. Based on our empirical findings, and as a next step, solutions to easing these data-related problems and information challenges are being developed. For example, applying digital technologies and data-science approaches could help reduce these challenges. However, more research is needed on how to use them to

facilitate consistent data flows along circular product lifecycles because closing information gaps along product- and material lifecycles is demanding but necessary in a circular economy.

Appendix A: Questionnaire

Demographic questions

- Industry affiliation of your company?
- Sales per business year?
- Current number of employees in your company (or subsidiary in the case of a group)?

Data availability

Response options availability: 1. not available at all, 2. scarcely available, 3. partly available, 4. largely available, 5. fully available

***Table A 1**. Survey questions about data availability.*

R-code	Questions
	How would you rate the availability of the following data that you (can) use for sustainable product management?
dq	Total energy consumption in the company
	Energy consumption per production plant
	Waste generation in the company
	Total emissions in the company
	Recycling rate in the company
	Other data: .....
	How do you assess the availability of the following data from your suppliers that you (can) use for sustainable product management?
dq	Information required by law (REACH, RoHs, Conflict Minerals, ...)
	Material composition of the component/product
	Production processes used
	Energy consumption of the production processes used
	Waste generation in the supply chain
	Social aspects in the supply chain
	Transport distances
	Emissions in the supply chain
dq	**How do you rate the availability of the following data from your customers and the end-of-life/post-consumer phase that you (can) use for sustainable product management?**
	User behavior (e.g. energy demand during product use,...)
	End-of-life routes
	Recycling rates

Data quality

Response options data quality: 1. insufficient, 2. low, 3. satisfactory, 4. good, 5. very good

Table A 2. *Survey questions about data quality.*

R-code	Questions
	How would you rate the quality of the following data that you (can) use for sustainable product management?

Key-Drivers shaping Circular Economy Transitions

System dynamics method in the circular manufacturing systems

Abstract

The complexity of circular manufacturing systems (CMS) plays a critical role in figuring out the best solution measures to accelerate and pave the transition pathway towards circular economy. The transition studies framework offers the ground to integrate Complex Adaptive Systems (CAS) and System Dynamics (SD) to build up a better transition towards a more circular economy (CE) in the manufacturing industry. The aim of this study is to identify the key-drivers that shape the value chain system's behaviour applying a multi-level perspective to better understand the CMS transition. The study uses a meso-level perspective to address value chain connectivity unfolding behavioural patterns between key-drivers in the Lithuanian CMS. Based on the systematic literature review, 12 key-drivers were identified as the causal enablers for the circularity transition. Moreover, empirical data was gathered from quantitative databases (OECD, Eurostat and Harvard Growth Lab) to further conduct interpretive systems dynamic modelling of the key-drivers' relationships. A panel of ten experts validated the key-drivers relevance, their direction and progression order, and set up the main challenges and the recommended solutions to engage a sustainable transition of CMS in Lithuania. Finally, the proposed CLD was validated by the experts' panel, and is expected to describe the behavioural patterns through feedback loops in the CMS. Interpretative analysis has pointed out the prescriptive divergences in comparison with the expected theoretical behaviour, therefore identifying the emerging challenges where the larger allocation of resources should be assigned to guarantee a successful circularity transition. Thus, the greatest challenges are expected to be addressed throughout the application of the solution measures proposed in the literature and adapted to the CMS for the Lithuanian national context. The originality of this study stands on taking a step back and trying to identify the causal drivers that shape the CE transition in the CMS, instead of looking independently at firms to disentangle the symptoms, barriers and business models in the micro-level.

Keywords: solution measures, multi-level perspective, complex adaptive systems, circular management systems, circular economy key-drivers

1. Introduction

Circular economy (CE) is understood as the regenerative system in which resource input and waste, emissions, and energy leakage are minimized while adopting cleaner technologies (Merli et al., 2018) and maintaining the value of products, materials and resources in the economy for as long as possible. The mainstream linear Manufacturing systems that run most economies in the world are orientated on the take-make-waste paradigm source of heavy pollution and resource-overconsumption, however without the systemic approach offered by the Circular Manufacturing System (CMS), traditional Manufacturing systems are not able to handle complexity issues and address unforeseen disruptions like the COVID-19 (Morales et al., 2022) or geopolitical conflicts like the Russian invasion in Ukraine that represent a risk for the value chain reliance (Herczeg et al., 2018; Ivanov & Dolgui, 2020; Kaplinsky, 2015). CMS entails a high level of complexity in terms of stakeholders interactions, physical, financial and information flows related to them. When value chain (VC) is approached as a system including the five CE building blocks: Waste management, Cleaner production, Intensifying and slow-down loops, Materials & eco-design and Vision strategies, identified in the literature (Galvão et al., 2020; Houssard et al., 2021; Werning & Spinler, 2020), the functional viability (Morales & Lhuillery, 2021), economic (Figge & Thorpe, 2019), environmental and social (Diaz Lopez et al., 2019) benefits get reinforced. Value chains entail interconnected supply chains able to withstand a disruption or series of disruptions when at the same time securing the provision of society and markets in a transition process (Chizaryfard et al., 2020; Morone, 2016), unfolding an ideal experimentation arena to quest on the behavioural patterns that frame the CE transition in the manufacturing sector (Bag et al., 2021; Magnusson et al., 2019).

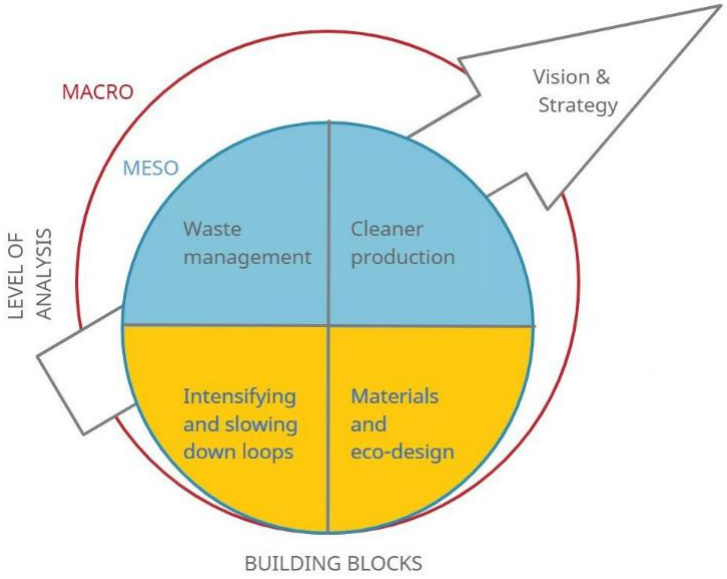

Figure 1. Introductory graphic abstract

Previous studies have already investigated how firms face the barriers of CE implementation (Diaz Lopez et al., 2019; Werning & Spinler, 2020); CE policy framework (L Milios et al., 2018); and, the circular key-drivers transition categorization in the manufacturing firms (Gusmerotti et al., 2019), but herein we look to reposition the research focus in the behaviour key-drivers of circularity (Gusmerotti et al., 2019; Tura et al., 2019) instead of the symptomatic barriers by asking questions about causal behaviours relationships (Guzzo et al., 2022; Morales & Lhuillery, 2021) of CE transition in the value chains. Transition from linear to a circular manufacturing ecosystem poses a major challenge for manufacturing companies because it requires them to be able to deal with complexity of coordinated actions and investments of multiple actors across the value chain (Ghisellini et al., 2016; Parida et al., 2019) and integrate the systemic approach that unfolds the existing behavioural patterns (Diaz Lopez et al., 2019). The aim of this study is to identify the key-drivers that shape the value chain system's behaviour applying a multi-level perspective to better understand the CMS transition. To clarify the objectives and improve the readability of this study, the definition of key concepts such as the multi-level perspective framework, the complex adaptive systems of the value chains and the systemic approach in the CMS are provided in the literature review section.

Herein, the socio-technical transition framework with a multi-level perspective offers a systemic approach that allows the authors to answer questions such as: 1) Does the causal key-drivers of CE transitions can be addressed with a systemic approach in the value chain?, 2) And, if that is the case, And, what challenges do the territorial context step up to shape the CE transition in the CMS? To answer these questions this study identifies the 12 causal enablers for the circularity transition, then empirical data was gathered from macro-scale quantitative indicators applying a multi-level perspective framework. Complex adaptive systems (CAS) and the systems dynamic (SD) approach imply that while not all aspects can be controlled (Morone, 2016), a better understanding of the value chain interconnection can be inferred conducting SD causal key-drivers analysis, interpreting the quantitative macro-scale indicators collected from the databases and validated by the panel experts. This study also intends to identify the direction and progression order of relationships among the key-drivers, and offers pragmatic insights about the main challenges identified in the concerned territory and the recommended solutions to engage the CMS transition in Lithuania (Geissdoerfer et al., 2017; Roggero et al., 2018).

Although manufacturing companies play a small role in a product's life cycle, they exert great influence on both the user and the product's end of life through product development and design (Bjørnbet et al., 2021). Therefore, in this study we are focusing on the CMS, one of the main CE research thematic areas (Morales et al., 2021) embedded in the closing and extending loops principles. However, we address the manufacturing sector without disregarding that, boundaries between sectors are blurring, and "manufacturing" increasingly represents the entire value chain of producing goods. Based on the existing literature about the key-drivers (Tura et al., 2019), authors identified the variables influencing CE transition in the Manufacturing systems, and using these findings as

conceptual ground, authors developed the systemic model under which behavioural relationships were structured based on key-drivers. Starting from a generalized investigation of the literature-based framework of CE key-drivers and the circularity of building blocks, the research method uses the information obtained from the systematic literature review (Morales et al., 2021) to understand the key-drivers interactions needed to build the Stocks and flows diagram that uses the statistical databases as inputs to assess the effect of business strategies and policy interventions on key-drivers presented in the Causal Loop Diagram (CLD).

2. Methods

The review of extant methods used in the literature identified the following five major methods for disentangling the complexity of the CMS key-drivers shaping the transition: 1) the indicators evaluation system framework (Marvuglia et al., 2018); 2) Discrete events multi-criteria framework (Vimal et al., 2019); 3) the Agent Based Modelling (Couto Mantese & Capaldo Amaral, 2017), 4) the Input-Output analysis (Li, 2012) and 5) the proposed System Dynamics (SD). SD is a method for studying complex non-linear problems able to embrace complexity and helps to understand how system structure leads to certain behavioural patterns, as shown by previous works such as J.J. Forrester in the book World Dynamics (1971), the famous work published by the Club of Rome, *Limits to growth* (Meadows et al., 1972) and System dynamics at sixty: the path forward published by Sterman (2018).

The present study is empirical (based on direct observations, experts panel opinions) and quantitative (statistical backward looking analysis of macro-scale indicators) to validate the causal relationship of macro-level behaviour in the CLD. Methodology includes relevant information obtained from the experts' opinions, composed by practitioners working in firms part of the VC and business managers and directors in Lithuania. The framework linking key-drivers with the CE building blocks aimed to define the relationship and structure of the CLD, which then set up the identified challenges in the territory and proposed the solution measures recommendations. The academic literature data sources confirm that quantifying the effects of CE initiatives and circular business models is difficult (Frishammar & Parida, 2019) as there is still a lack of suitable measuring tools.

As we can observe in Figure 2, the authors set the research protocol based on three consecutive stages:
Input, 2) Development and 3) Output. The input stage entails the design of the methodological boundaries of the CMS in Lithuania, the objectives, the systematic literature review, the quantitative macro-scale indicators, as well as the design of the Experts panel. In the second stage, the development of the research protocol includes Secondary data collection and Data analysis, using the inputs collected from secondary sources, Key-drivers relationship search, Panel of experts consultation and the CLD development. Finally, the Output stage entails the Causal Loop Diagram interpretative analysis, the key-drivers relationship validation, the proposal of a transition analysis framework linking key-drivers with interventions in the building block coping with measurable and objective

solution measures recommendations that tackle the most relevant identified challenges in the territory. The 3 stages methodology proposes means to measure qualitative and quantitative features in a reliable and replicable way to identify CE causal relationships in the manufacturing industry.

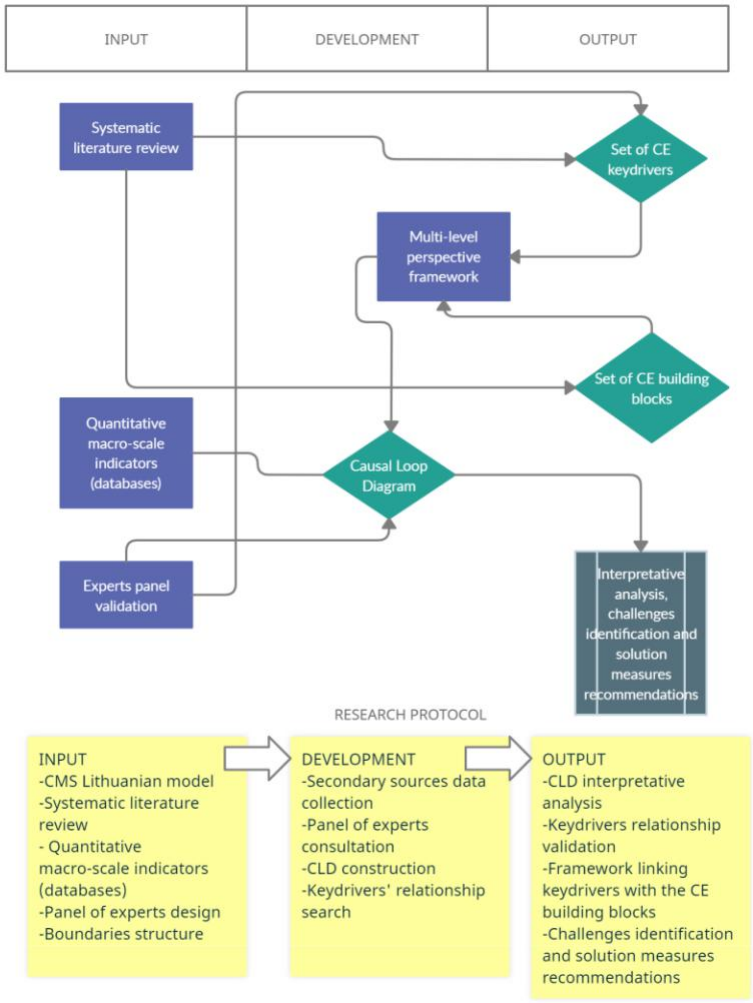

Figure 2. Research methodology steps

2.1. Key-drivers validation by the Expert panel

Figure 2 explains that one-step in the Input stage is the experts' opinions gathering. The research team followed the existing guides (Frost et al., 2020) and developed a robust expert identification and selection protocol to ensure the validity of outcomes and avoid potential bias. Following the protocol, the research team identified 20 experts potentially eligible. The study focused on Lithuanian experts to improve our understanding of the causal relationships and key-drivers of the CMS in the Lithuanian geographical and socio-economic outreach. Thus, rendering Lithuanian experts more eligible to participate. The study gather 2 groups of experts, one composed of 10 Lithuanian experts, inviting them to participate in the preliminary eligibility assessment step. And the second

group composed of 10 European experts to compare the Lithuanian circular manufacturing outlook with the overall European outreach and patterns. This preliminary step involved experts answering a few self-assessment questions to measure their familiarity and experience with the Circular economy phenomenon. Out of the 20 experts, 10 European and 10 specifically from Lithuania, 15 agreed to participate in the self-assessment step, out of whom 10 were identified as eligible to attend the expert panel meetings. As a result, ten experts participated in the expert panel-meeting step. Scholars and practitioners composed the experts, all with sheer experience collaborating with various Lithuanian programs and policies in related business contexts such as sustainable development, digital transformation, resilient smart economy, or circular economy.

Experts' opinions on the key-drivers of CE transformations were collected across the two online meetings. The nominal group technique (NGT) was used as the primary approach for idea generation and decision-making across the expert panel meetings. NGT offers various advantages, such as encouraging and offering fair opportunities for contributions from all experts, and its application has been widely acknowledged within the prior SD-based studies (Ghobakhloo, 2020). During the first meeting, the 12 key-drivers and their description identified across the systematic literature review were presented to the experts. Besides recommending a few minor corrections to the labelling, experts confirmed the overall structure and inclusiveness of the enablers. Experts further identified the contextual relationships among each pair of enablers across the second meeting too. Merely, the computation of macro-scale quantitative indicators is not sufficient, as it is essential to check whether the obtained outcomes are consistent or not with the observed reality.

2.2. Statistical backward looking analysis of quantitative macro-scale indicators

This section details the methodological approach. First, empirical analysis is employed using a 10 years dataset ranging from 2010 to 2019 for all variables except *High-technology manufacturing and knowledge-intensive high-technology services* only available with a span from 2012–2019, as reported by Eurostat (2022). Suitable statistical analysis considering this type of data is collected for Lithuania. The variation for each variable is analysed yearly and is considered as a yearly increase only if the comparison with the previous year is higher than the average inflation calculated for the 10 years period (2010-2019) inflation calculated at 1.84% according to the Bank of Lithuania. If the variable comparison between the previous year period and the present period is less than the inflation rate average 1.84% and more than a decrease of -1.84%, then we consider it a steady variable. The overall variation trend per variable in the period (2010-2019) is calculated by adding up every year trend to avoid overfitting bias, which occurs when the data fits too well if the variable shows low bias but high variance. Overfitting is often a result of excessively complex models, and it can be prevented by fitting multiple models and using validation or cross-validation to compare their predictive

accuracies on test data. Moreover, the most frequent tendency (increase, decrease or steady) is considered as the variation trend for the entire observed period.

Lithuanian CMS is an outstanding case study for analysis because it offers a strong vertical and horizontal interconnection in the VCs when it refers to comparing different CE enablers categories (economic, institutional, organizational, social and environmental) composing the VC in the CMS. Lithuania is a country which has done well in the last decade, moving up in the CE indicators ranking, especially on per capita waste production and recycling rate per country performance (Ecopreneur, 2019), even if the manufacturing system in the country is taking the role of follower, emphasizing the benchmarking of standards and regulations imposed from the leading members of the VC. The industrial sector contributes 25.5% to the GDP and employs around 25% of the active population. The main industrial sectors in Lithuania are electronics, chemical products, machine tools, metal processing, construction material, household appliances, food processing, light industry (including textile), clothing, and furniture. The country is also developing oil refineries and shipyards. The manufacturing sector alone contributes to 17% of the country's GDP (Dagilienė et al., 2021). To the best of our knowledge, systemic models have been previously used (Bocken et al., 2017; Wasserbaur & Sakao, 2020) to investigate the CMS in other specific value chains like plastics (Foschi & Bonoli, 2019) and biomass (Morales et al., 2022) through a macroscale approach, but none of them offer objective guidelines to the practitioners regarding the interventions (bottom-up/top-down) choices that reinforce the CE transition in the VC at the CMS. As emphasized by many scholars, the new challenge of the CE can only be addressed by having a comprehensive framework including all five building blocks.

2.3. System dynamics methodology

SD is a methodology able to define the boundaries of the value chain in the CMS and with that defining the complexity of the model according to the available resources to solve it. The SD models are able to describe the structure of the CMS, even when the behavioural decision variables coming from each one of the actors of the system are nonlinear. To do so, SD modellers need to integrate all the available quantitative and qualitative empirical data to corroborate the significance and validity of the variables involved in the CLD and its parameters, building confidence in its results. SD not only can deal with deterministic compartment models that represent individual agents, using discrete time and stochastic elements, but, it can also be implemented using continuous time and state variables representations and deterministic uncertainty, which is also compatible with the feedback information systems (Roci et al., 2022).

The SD method has recently attracted the attention of the scientific community (Alamerew & Brissaud, 2020; Franco, 2019; Wasserbaur & Sakao, 2020) and the broader society because of its ability to anchor itself in the

present and propose meaningful and viable scenarios to the future. Despite the advantages of SD methodology to analyse complex systems in the quest for complex non-linear solutions, this methodology has rarely been used to analyse macro-level transition drivers in the CE seeking to get a better understanding about CMS, with very few exceptions like the research design including a comparison of two countries published by Levänen et al (2018) that explores battery recycling in Finland and Chile. Some gaps have been identified when integrating the CAS and SD in a territorial approach, i.e. behavioural key-drivers shaping the CE transition in time and space. Evidence confirms that CE transitions in the Lithuanian manufacturing industries should be analysed from a meso and macro level perspective, acknowledging that VC and actors adapt each time according to the socio-economic context. Furthermore, Albino et al. (Albino et al., 2016) provide another system study that intends to understand the impact of behavioural transitions between multiple input and output suppliers/receivers. We observe in Table 1, the subset of drivers composing each one of the12 key-drivers that engage a systemic relationship in the CMS and are key for the understanding of the CE transition, according to the existing scientific literature. We use 12 indicators and proxies, one for each one of the identified key-drivers for the sake of simplification in the CLD. Among the concerned indicators and proxies we found traditional statistical sources (Eurostat, OECD database and one index from the Harvard Growth Lab). The outputs provided by the analysis of the macro variables are complemented in the discussion section with the insights obtained from the panel of experts to disentangle the structural behaviour of the CMS. There are some other variables identified in the literature but regarding the missing statistical data or proxies available and because they were not significant enough to change the causal relationships in the CLD, we decided not to include them in the calculations. Moreover, according to the experts' opinions those side variables are: Modular design, Company brand differentiation, Alternative finance and, Regulation & standards.

Table 1. Circular economy key-drivers composing the Causal Loop Diagram

CE CATEGORIES	KEY-DRIVERS	INDICATORS & PROXYS	MEAN	STANDAR DEVIATION	TREND	10 YEARS PERIOD (2010-2019) VARIATION
ENVIRONMENTAL	Materials circularity	Circular material use rate	3.95	0.4249	STEADY	11%
	Innovation	R&D expenditure (% of GDP) in the Business entreprise sector	0.3	0.0650	STEADY	22%
	Resource productivity	Resource productivity (ratio GDP/DMC)	1.33083	0.0718	STEADY	5%
	Competitivity	Economic complexity index	0.718	0.0703	INCREASE	10%
ECONOMIC	Value-added	Value added by Manufacturing in percentage	19.1691	0.7962	STEADY	4%
	Internationalization	Exports (million euros)	23757.07	3795.9078	INCREASE	16%
SOCIAL	Wages	High-pay wages level (thousand persons)	25.27	2.0447	DECREASE	8%
	Government revenue	General government revenue, (Thousand US dollars/capita)	9961.611	2005.8465	INCREASE	20%
	Taxation, incentives, and subsidiary policies	General government spending. Environmental protection+Education, % of GDP	5.672105	0.7148	DECREASE	13%
INSTITUTIONAL	Regulation and standards	Recycling rates of packaging waste for monitoring compliance with policy targets	60.97	3.8158	INCREASE	6%
	Skills Upgradability	High-technology manufacturing and knowledge-intensive services (percentage of total employment)	2.5125	0.3444	INCREASE	14%
ORGANISATIONAL	Skills and competences	Employment by tertiary level (% total employment of 25-64 year-olds)	89.48	1.4462	STEADY	2%

There are some other drivers observed in the scientific literature that are worth to be mentioned in this study even if they are not included in the CLD construction and are hard to grasp due to the lack of quantitative macro-scale data. The practitioners and the academic community need to be aware about the role played by the following cross-sectional drivers: 1) Consumer awareness, market expectations (Lieder & Rashid, 2016); 2) Overarching policy framework for product life upgradability (Leonidas Milios, 2021); 3) Change of mindset (Geissdoerfer et al., 2017; Sousa-Zomer et al., 2018); 4) ecological responsibility through modular design (Dangelico & Pujari, 2010; Mateus et al., 2020); 5) Company brand and structure differentiation (Sousa-Zomer et al., 2018; Tura et al., 2019); 6) New routines and processes (Parida et al., 2019) improving client satisfaction (Geissdoerfer et al., 2017; Seuring & Müller, 2007); as well as measures like 7) Brand company differentiation; 8) Modular design, 9) Alternative financing, 10) Partnership & collaboration; and 11) Technological and information drivers entailing Digital technologies for remanufacturing and reuse activities are relevant for the circular economy transition analysis in the Manufacturing sector (Parida et al., 2019).

3. Results and Discussion

Within the SD framework, Causal loop diagrams (CLD) can be thought of as sentences that are constructed by identifying the key variables in a system (the variables) and indicating the causal relationships between them via links (the loops). By linking together several loops, you can create a concise story about a particular problem or issue. A CLD consists of four basic elements: the variables, the loops between them and, the signs on the loops, which shows what type of behaviour the system, will have. By representing a problem or issue from a causal perspective, you can become more aware of the structural forces that produce conflicting behaviour.

Feedback processes governing key elements of a CE transition in the CMS. CLD makes use of arrows to indicate causal relationships between system variables. These relationships can be either positive (represented by a plus sign) or negative (represented by a negative sign). A positive relationship, known in SD as reinforcing feedback, implies that, if variable X is connected to variable Y, they move in the same direction (an increase in X will lead to an increase in Y, and a decrease in X will lead to a decrease in Y). A negative relationship also known as balancing feedback suggests that the variables move in opposite directions (an increase in X will lead to a decrease in Y, and a decrease in X will lead to an increase in Y). Solution measures embody complex efforts to change the behavioural structure of the system, influencing feedback loops, where balancing feedback works as control mechanisms and reinforcing feedback amplifies system change. For example, an intervention that increases Skills and competences in the labour market entails a control mechanism on the Wages, triggered by the offer increase of the workforce pool with the skills and competences required for the CE transition. Therefore, Skills and competences have an amplifying effect over Wages in the CMS when allocating the limited resources among the most competitive and frontrunner firms in the VC.

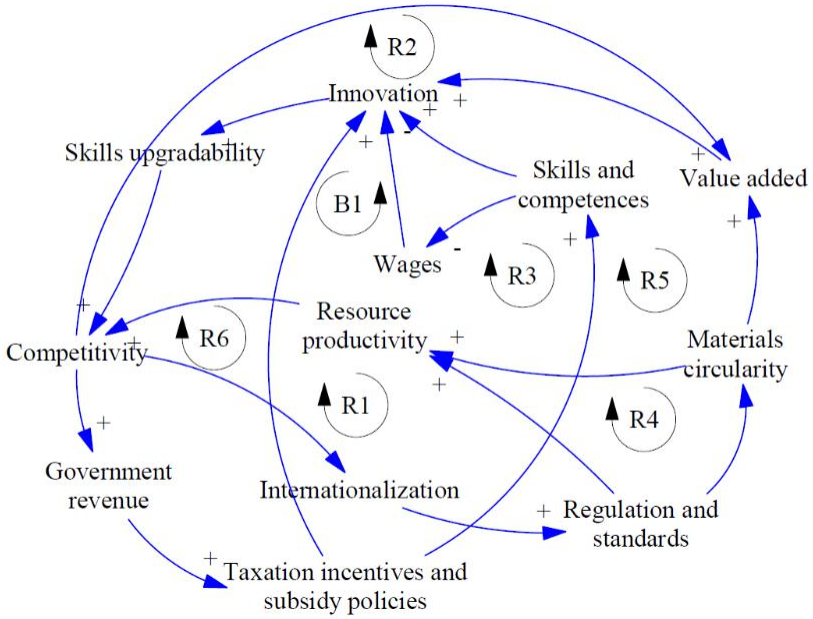

Figure 3. Causal Loop Diagram of the CE key-drivers engaging CMS transition

Herein, we identify six reinforcing loops (R1, R2, R3, R4, R5 and R6) and one balancing loop (B1) were identified in the Causal loop diagram. The identified loops need to engage more than two variables (bilateral relationship) to be considered in the CLD. There are feedback effects created by reinforcing and balancing relationships in the current structure of the CMS, which have an impact on the likelihood of CE transition in the CMS.

The circularity implementation in VCs is an essential component for the CMS to improve global sustainability. However, if adopted wrongly, the organizations will face a high loss of investment costs individually and collectively. According to the findings of this paper, we can show evidence claiming that the key-drivers of CMS transitions depend on the VC context based on the socio-technical transition framework. Hence, it becomes essential to identify the complexity of the causal relationships, the main challenges and the solution measures required for a successful adoption of CMS. Based on the CLD integrating SD within the multi-level perspective theory we counter the bottom-up hierarchical framework proposed by Kumar et al., (2019). This study claims that systems approach offers to decision-makers and stakeholders the possibility to deal with CAS and improve our understanding regarding causal relationships among key drivers in the CMS transition in a geographic specific context like Lithuania. The empirical evidence found in this study helps to answer two research questions stated in the CMS case study where a multi-level perspective framework is applied to analyse the CE transition. The systemic construction of causal loops, drivers and interrelations in the CLD aims to improve our CMS understanding using CAS and SD to identify the solution measures that could counterbalance or amplify the circular patterns that address the greatest challenges for the CE transition.

From the empirical observations in the Causal Loop Diagrams in Figure 3, we identified some discrepancies between the expected causal relationship direction according to the literature and the observed behaviour of the quantitative key-drivers collected for Lithuania in the databases during the 2010-2019 period. The conflict could be categorized in major discrepancies and minor discrepancies. The minor discrepancies identified in the Lithuanian CMS are those that are not opposite, meaning that the deviation from the expected behaviour is less than the difference of the Lithuanian inflation rate. For example, the Innovation variable observed in R2, R3, R5, R6, B1 and B2 shows a steady trend, whereas Skills upgradability experiences an increase higher than the inflation rate during that period. The previous relationship could be explained by exogenous variables impacting Skills upgradability variable or because the Innovation mechanisms in Lithuania are not triggering the prescriptive causal effect, and therefore needs to be resettled. Other minor discrepancies are observed in the following variables: Regulations & standards, Resource productivity and Taxation incentives and subsidy policies. The major discrepancies in the causal effects consist of relationships triggering the opposite effect to the one expected in the literature. In the Lithuanian CMS the two variables present major discrepancies with the CMS theoretical framework, the key-driver of Government revenue observed in the R3 and B2; and Skills upgradability observed in R3. The *Skills upgradability* and *Government revenue* were identified as the two major discrepancies of the causal effects with the theoretical framework utilized for the CMS transition in Lithuania, indeed they embody one of the most relevant outcomes of this study.

The authors claim that most of the interactions encountered in the literature analysis (Razzaq et al., 2021; Tseng & Bui, 2017) were found to be supported by the empirical observations in the CLD, with the exception of the two major discrepancies observed in the CMS in Lithuania: the Government revenue, and Skills upgradability.

Table 1. Causal table of proposed solutions in the CMS Lithuanian context to address the major discrepancies identified

MAJOR DISCREPANCIES	COMPOSING ELEMENTS	PROPOSED SOLUTION MEASURES
Government revenue	High-cost of sustainability adoption	the collaboration and coordination among value chain members
		the Adoption of Smart factory components
	Lack of availability of resources for CE transition strategies	the adoption of industrial ecology initiatives
		the understanding of economic and social benefits
Skills upgradability	Ineffective employees training for sustainability	the Adoption of advanced quality improvement techniques
		the Adoption of advanced predictive maintenance systems
	Lack of effective employees engagement and empowerment	the Digitalisation of supply chain activities
		the Adoption of advanced machine learning algorithms
	Non consideration of human-factors for CE	the Integration of digital and physical systems
		the Adoption of advanced machine learning algorithms

Government revenue discrepancies are explained by Yadav et al., (2020) as the inability to overcome some challenges related to the High-cost of sustainability adoption and the Lack of availability of resources for CE transition strategies. The measures proposed in the literature to solve the High cost of sustainability adoption are the collaboration and coordination among value chain members and the Adoption of Smart factory components. The solution measures to address the Lack of availability of resources are the adoption of industrial ecology initiatives and the understanding of economic and social benefits.

Skills upgradability is here understood, as the highly skilled STEM workers required engaging the transitions in the Manufacturing sectors able to power the national economy and build economic opportunities in the high technology manufacturing and Knowledge intensive services. The increase on Skills and competence was identified in this study as one of the main challenges in Lithuania to propel CMS transition through the training of highly educated professionals and public policies regulating the reduction of Wages below a certain

threshold that avoid the brain drain of the creative demographic sector to other regions that propose better salaries.

Moreover, Skills upgradability discrepancies with the theoretical framework are explained by Yadav et al., (2020) as the inability to overcome some challenges related to the Ineffective employees training for sustainability, lack of effective employees engagement and empowerment and the Non consideration of human-factors for CE transition strategies. The measures proposed in the literature (Yadav et al., 2020) to solve the Ineffective employees training for sustainability are the Adoption of advanced quality improvement techniques and the Adoption of advanced predictive maintenance systems. The increase on Skills and competence training was identified in this study as one of the main challenges in Lithuania to propel CMS transition through highly educated professionals and public policies regulating the reduction of Wages below a certain threshold that avoid the brain drain of the creative demographic sector to other regions that propose better salaries. The solution measures addressing the lack of effective employee engagement and empowerment are: the Digitalisation of supply chain activities, and the Adoption of advanced machine learning algorithms. The solution measures to address the Non consideration of human-factors for CE transition strategies are the Integration of digital and physical systems and the Adoption of advanced machine learning algorithms, again. Policy makers are though advised to conduct campaigns that could assist in enhancing the nation's economy.

In practice, it is extremely difficult for practitioners to simultaneously execute all the solution measures required for manufacturing ecosystems, measures that cover different scales of analysis. A huge challenge in the implementation of CE transition emerge in the form of the bottom-up hierarchical framework (Kumar et al., 2019), suggesting that the transition process should start from micro level with enterprises and move towards the macro level, where the transformation process should be accomplished, but just after being consolidated in the firms. The bottom-up hierarchical framework claims that each level forms a basis for the following level, neglecting the systemic and simultaneous features of the multi-perspective theory applied to CE transition, its challenges and solution measures. The bottom-up hierarchical framework engages a logical fallacy stating that if CE is applied successfully at firms level, then macro-level landscape will ensure political, institutional and socioeconomic conditions for the CE transition. If the macro-level landscape ensures political, institutional and socioeconomic conditions for the CE transition, then CE will be applied successfully at the firm's level. While this may appear to be perfectly fine logical reasoning, it is not a valid argument because the first statement does not logically guarantee the second. If we are not certain about the causal effect and the direction and magnitude of this influence, any intervention would be true but the conclusion would be incorrect. Therefore, in our study we propose a systemic approach to both scale levels: 1) meso-level value chains where the functional viability is established and; 2)

macro-level landscape ensuring the political, institutional, economic and social conditions required to engage the CE transition.

The more variables we have in a system, the more complex the CMS becomes, facing challenges like the transmission of huge quantities of knowledge across large networks of people, the cooperation with multiple suppliers/receivers, transaction costs, and transportation costs, among others. Multi-product and multi-firm interactions in the VC have proven the potential of being systemically approached, integrating context-specific allocation decisions of the CMS through feedback loops, engaging specific outcomes like reverse supply chain, downcycling or cascading of materials, energy or by-products on it. The key-drivers identified in the CLD and the causal relationships portrayed will assist policymakers and stakeholders to build a systemic and complex adaptive understanding of the CMS orienting efforts towards high tech and knowledge intensive solutions in Lithuania. It is therefore expected that Lithuanian public actors develop policies to improve Skills upgrading and Governmental revenue collection strategies. Herein, the findings suggest that both levels (meso and macro) together with the bottom third level (the micro-level) represented by the individual firms entail a complex dynamic CMS. In the CMS we found evidence about the two-ways feedback loops between the macro-level landscape and the meso-level dominant regime. Low complexity productive structures like the observed in less industrialized countries like Lithuanian where high skills labour force is limited, stresses the structural investment needs for Skills upgrading, research & development to reach the breakthrough technology point and increase investment in targeted Science, Technology, Engineering, and Mathematics (STEM) training and education that allows Innovation and Competitivity increases (Hallward-Driemeier & Nayyar, 2017).

4. Conclusions

The present study supplies breakthrough insights to identify the key-drivers and the causal relationships enabling the CE transitions on the macro-scale level and the solution measures that have the potential to amplify or counterbalance the behavioural patterns in the CMS. Indeed, the study offers a tool able to improve the current understanding of the CMS using CAS and SD to shape the CE transition. To do so, this study identifies the key variables influencing CE transition in the CMS, and uses the causal relationship direction and progression order as the empirical ground under which CE interventions could be proposed to shape the transition. All at all, the present study contributes to look at the bigger picture in the current state of the art which focuses in the symptomatic effects observed in the barriers and business models as approached by Tura et al., (2019) rather than disentangling the behavioural key-drivers of the VC system approached through the dominant regime in the meso-level, a theoretical construction influenced by the multi-level perspective of transition studies (Morone, 2016).

Furthermore the authors suggest approaching the CMS as a dynamic system where the three levels (micro, meso and macro) wave causal relationships and feedback loops between the Macro-level landscape, the meso-level dominant regime and the Micro-level innovation niche. Finally, the study suggests that CE transitions in the manufacturing industries respond to contextual (geographical, political, social and economic) differences inherent to the VCs aggregated in the CMS of each particular sector.

We found empirical evidence about the advantages of representing a problem or issue from a causal perspective, because decision-makers become more aware of the structural forces triggering puzzling behaviour when they are able to identify the causal loops driving the transition process in the CMS. Herein, we claim that CMS represents an ideal arena to integrate the CAS and SD into a macroscale territorial system able to engage CE transition in the VC. The present study supports this comprehensive view and offers additional empirical evidence to conclude that CAS and SD methods fill existing gaps regarding the systemic and complexity analysis of the CMS models. Moreover, this study provides some solution measures and recommendations on how to tackle the biggest CE challenges per territory, without simply replicating already existing waste management formulas of developed countries. Thus, to escape from the trap of including recycling into the linear economy paradigm, the transitions in developing countries like Lithuania are composed by solution measures like the adoption of industrial ecology initiatives and the understanding of economic and social benefits; and the Adoption of advanced quality improvement techniques and advanced predictive maintenance systems. The adoption of advanced quality improvement techniques and predictive maintenance systems target specially Science, Technology, Engineering, and Mathematics (STEM) training and education programs implementation, because they increase the available pool in high-technology manufacturing and knowledge intensive services.

This study have identified either the implications of a CAS and systems approach in the CMS using a comprehensive perspective integrating multi-level transition theory, which changes fundamentally the needs of simultaneous interventions in all three levels (micro, meso and macro) to propel the CE transition within a specific socioeconomic context looking to place people and societal needs in their very centre of the structure. The methods and diagrams presented here are subject to certain degree of estimation errors and caution is advised while interpreting and generalizing the conclusions drawn in this study to different countries and different sectors. Future studies should collect data from other countries in Europe to validate or adjust our findings. This study focuses on methods able to handle SD and CAS at CMS, because you can only improve what you can measure, and CMS represents an ideal arena to put on trails the implementation of smart coding systems, data analytics in multi-dimensional strategic evaluation and blockchain technologies among others. The EU Green Deal is a major driver for CE in the coming decade but its success depends on complex adaptive and systemic action for socio-ecological wellbeing. The political agenda addressed in the European Commission's Green Deal is setting CE as the required

transition model to trigger the path for the Industry 5.0 transition driving a fundamental transformation of Europe's economies and societies. Further research avenues for CMS and CAS are identified in the circularity assessment indicators, starting by measuring the overall performance of the VC in terms of their impacts. The originality of this study stands on taking a step back and trying to understand the value chain's complexity and systemic condition is the interwoven relationship of behavioural key-drivers able that shape the causal relationships in the CE transition according to the geographic context of the CMS, instead of looking independently at firms to disentangle the symptoms, barriers and business models in the micro-level.

Abstract

Since its first appearance in literature around 2015, the innovative concept of Circular Bioeconomy (CBE) has raised in popularity being identified as a strategic solution for facing the present and upcoming environmental challenges and for bringing about a sustainable decisive shift in current linear economic systems. In this regard, an eloquent example of the centrality acquired by the notion of CBE can be observed in the renewed ecological narrative promoted by the European Commission and sculpted in two pivotal documents, the Updated Bioeconomy Strategy (2018) and the European Green Deal (2019), in which CBE is interpreted as a central framework to meet the Sustainable Development Goals. Nonetheless, despite its growing echo in both academic and political debate, we cannot deny that we are dealing with an extremely controversial and nebulous phenomenon that poses enormous challenges, especially from a theoretical point of view. In particular, the unsolved ambiguity that surrounds the relationship between its two building blocks, bioeconomy and circular economy, results in an obvious difficulty of drawing clear and understandable boundaries and increases the risk of spreading another chameleonic notion. Therefore, the need for systematic categorization is more than evident to unlock the full potential of the paradigm and ensure its scientific stature trying to avoid the shallowness of the "buzzword effect" by investigating the dynamics intrinsic to recent history of this emerging concept.

In this context, our research goal is to contribute to a better and deeper understanding of the emerging paradigm of CBE and its role in the global challenges by exploring the debated relationship between its building blocks. We also aim to contribute to clarifying the interaction of CBE with other popular and partially overlapping conceptualizations, first and foremost green economy. Pursuing this goal, we first

perform a bibliometric network analysis for assessing trend and patterns within a sample of papers selected according to specific and predefined inclusion criteria to better reflect the fragmented composition of the research field. Secondly, through screening and coding the selected papers, we conduct a content analysis in order to understand the distribution in the sample of the different visions of the bioeconomy. Finally, in the light of the results of the content analysis, we carry out a systematic literature review to verify which bioeconomy narratives has the most connections with circular economy vision and how these connections are declined especially in terms of weak or strong sustainability. The present paper reports the results of the first step of this methodological structure that is related to the bibliometric analysis.

Keywords: Circular Bioeconomy, Bioeconomy, Circular Economy, Literature Review, Bibliometric Analysis

1. Introduction

In the list of concepts proposed as a panacea to the major environmental challenges of our time (Giampietro, 2019), a new term has recently emerged: Circular Bioeconomy (CBE). Since its first appearance, around 2015, what, generally speaking, is considered as the combination of Bioeconomy (BE) and Circular Economy (CE) has known a considerable success gaining increasing recognition as strategic solution to impart a sustainable transformation to the current economic system. Undoubtedly, by offering the possibility of synthesising how resources should be used, CE, and what resources should be used, BE (D'Amato et al., 2017), the concept has broken as a game changer into the sustainability debate raising expectation and optimism among practitioners. In this regard, the transition towards CBE is pointed as pivotal in the recent revision of the European Union's Bioeconomy Strategy which affirms the need for the bioeconomy to be inspired by the principles of circularity (European Commission, 2018a). However, the rising popularity, both academic and political, of the notion does not seem to be supported by adequate theoretical elaboration posing the risk of a chameleon concept exposed to the spectrum of the "buzzword effect". The present study constitutes the first step of a complex research path directed to trace the theoretical web that inspires the concept of "Circular Bioeconomy" (CBE) and to lay the foundations for a more conscious and effective implementation of it, especially at the level of national and international environmental policies. In particular, with this preliminary work, we aim to explore the evolution of academic literature on CBE in the attempt to answer the following research question: which visions of Bioeconomy (BE) are most common in the new research field of CBE? Indeed, in a literature review that has become pivotal among practitioners, Bugge, Hansen, and Klitkou (2016) identified three ideal visions of BE: Bio-technology vision, Bio-resource vision, and Bio-ecology vision. We decided to apply this proposed distinction as theoretical guide in the effort to respond to the need for more systematic categorisation of the notion of CBE and provide a first conceptualisation of its main thematic streams. In this way, we expect to improve the comprehension of the dynamics that involve the two

building blocks of CBE, BE and Circular Economy (CE), moving from the assumption that, for drawing clear and understandable boundaries of the paradigm, is essential to clarify the relationship of its components.

2. Methods and Materials

The categorisation of the notion of CBE is delineated using as theoretical guide the three ideal visions of BE proposed by Bugge, Hansen, and Klitkou (2016) summarised in Table 1: Bio-technology vision, Bio-resource vision, and Bio-ecology vision. The first two narratives of BE are evidently characterised by a strong technical and economic perspective. While the Bio-technology vision urges for investing in the development and application of bio-technology research in different economic sectors, the Bio-resource vision emphasises the role of bio-resources capitalization as main drivers for economic growth through the creation of new value chains. Adopting a diametrically opposed approach, closer to the social and environmental dimension of sustainability, the Bio-resource vision focuses on the promotion of biodiversity and conservation of ecosystems through designing circular and integrated process especially at regional level. This means that if the first and second visions have a more manifest business as usual connotation assuming a positive relationship between technological development and environmental sustainability, the third one calls for more circular and self-sustained production systems in a contest of strong sustainability able to avoid soil degradation and maintain the capacity of ecosystem services.

Table 1. *Key characteristics of the three Bioeconomy Visions from Bugge et al. 2016*

	The Bio-Technology Vision	The Bio-Resource Vision	The Bio-Ecology Vision
Aims & objectives	Economic growth & job creation	Economic growth & sustainability	Sustainability, biodiversity, conservation of ecosystems, avoiding soil degradation
Value creation	Application of biotechnology, commercialisation of research & technology	Conversion and upgrading of bio-resources (process oriented)	Development of integrated production systems and high-quality products with territorial identity
Drivers & mediators of innovation	R & D, patents, TTOs, Research councils and funders (Science push, linear model)	Interdisciplinary, optimisation of land use, include degraded land in the production of biofuels, use and availability of bio-resources, waste management, engineering, science & market (Interactive & networked production mode)	Identification of favourable organic agro-ecological practices, ethics, risk, transdisciplinary sustainability, ecological interactions, re-use & recycling of waste, land use, (Circular and self-sustained production mode)
Spatial focus	Global clusters/ Central regions	Rural/Peripheral regions	Rural/Peripheral regions

In order to portrait the BE discourses that operate inside the new paradigm of CBE, we carried out a comprehensive bibliometric analysis though the combination of the main bibliometric procedures, i.e. performance analysis and science mapping (Cobo et al., 2011). While performance analysis tries to measure the performance of different research constituents, such as authors and institution, in a specific research field by examining their contributions

to it, science mapping investigates the relationships between research constituents to uncover the cognitive structure and dynamics of a scientific fields (Donthu et al., 2021; Župič & Čater, 2015). Conscious of this, the research has been designed not only to account the contributions of research constituents, but also to construct a powerful "visual" holistic representation of the inner intellectual interactions and structural connections among bibliographic data (Donthu et al., 2021). As previous works have done in the field of CE and BE, we intend to reinterpret the traditional quantitative methods of bibliometric analysis to extract qualitative information from statistical observations (Konstantinis et al., 2018). Indeed, with their quantitative rigor, bibliometric methods can bring a degree of objectivity into the subjective evaluation of literature providing a valid instrument for discover thematic patterns especially in a wide breadth of studies (Garfield, 1979; Župič
Čater, 2015). However, the aim of this contribution is not to report a mere bibliometric exercise, but to interpret the results of both performance analysis and science mapping through the lens of BE visions in the effort to provide an exhaustive response to the research question. For this reason, we propose a methodological progression that allows the topic to be explored with an increasing level of detail.

Firstly, the literature sample was built. Data mining was conducted on January 6, 2022 through Scopus database using the following Boolean string "circular bioeconomy" OR "circular bio-based economy" OR "circular bio-economy" within titles, abstracts and keywords. The search was further refined by limiting the document typology to articles and reviews and selecting English as language. Instead, concerning the time range no initial deadline was applied, while it was considered appropriate to exclude 2022.

Consequently, once checked for duplicates, publications were collected and uploaded in SciVal, a web-based analytics solution developed by Elsevier that, using Scopus data, enables researchers to evaluate research activities from a variety of perspectives (Elsevier, 2022). Exploiting the functionalities offered by the two bibliometric platforms, Scopus and SciVal, we tried to get an overall picture of the field and its constituents by applying some of the main performance analysis metrics: number of publications per year; total and average citations; number of contributing authors; identification of central journals, countries, founding sponsors and subject areas.

Therefore, to give a more in-depth answer to the investigated research question and verify the validity of the hints obtained from the performance analysis, we reviewed the identified literature through some classical science mapping techniques, i.e.: Citation Analysis, Bibliographic Coupling and Co-word Analysis. Citation Analysis is known as a basic instrument to implement science mapping and aims to ascertain the most influential publications in a research field by the number of citations that it receives. In other terms, this type of analysis determines the impact of a publication moving from the assumption that citations can reflect its intellectual quality and stature in an objective and straightforward way (Donthu et al. 2021; Pieters & Baumgartner, 2002; Stremersch, Verniers, & Verhoef, 2007). After using this measure of influence (Župič & Čater, 2015) for getting a preliminary idea about

the thematic orientation of the examined area, we assessed bibliographic overlap of the sample through Bibliographic Coupling. This notorious science mapping technique allows to link source documents together (Baker, 1990), assuming that their sharing of common references may be symptomatic of potential content similarity (Donthu et al. 2021; Kessler, 1963; Weinberg, 1974). Although bibliographic coupling offers, in line with the purpose of the study, an effective tool to understand how knowledge is combined among sets of publication (Donthu et al. 2021; Biscaro & Giupponi, 2014), the similarity association established tends to be considered static, because makes it difficult to determine for each document the reason behind the same reference. To compensate these limitations, typical of citation-based methods, we decided to combinate it with a more dynamic and powerful tool for discovering knowledge infrastructure of a research domain, i.e. Co-word analysis (Baker, 1990; Ferreira, 2018; Župič & Čater, 2015). Unlike previous applied science mapping technique, this method doesn't employ cited or citing publications as focal point or proxy, but elects words as the unit of its analysis (Donthu et al. 2021). By extracting words from "author keywords", "article titles", "abstracts" or "full texts" co-word analysis focuses on the actual content of the publication itself aiming to discover thematic linkages in the co-occurrence of pairs of words (He, 1999; Donthu et al. 2021). This because the fundamental assumption underlying this procedure is that the frequency with which words appear together should be indicative of their conceptual connection. Since the quality of results of a co-word analysis may be affected by the type of words chosen or the statistical method adopted (He, 1999; Župič Čater, 2015), this study proposes a co-word analysis structured on a double level using text data extrapolated from both titles and abstracts. To perform in an intuitive graphical way both Bibliographic Coupling and Co-word analysis (Donthu et al. 2021), all the data were also exported in CSV format and uploaded in VOSviewer. This is a software developed by van Eck and Ludo Waltman for creating and visualising bibliometric networks, that is particularly suitable when working with larger amount of bibliometric data.

3. Results and Discussion

This section illustrates and discusses the results achieved with the illustrated research method by organising them in two paragraphs dedicated, respectively, to performance analysis and science mapping.

3.1 Performance Analysis

The Scopus database search delivered 458 publications, 293 articles and 165 reviews dating from 2016 to 2021, that include the words "circular bioeconomy" OR "circular bio-based economy" OR "circular bio-economy" in title, abstract, and keywords.

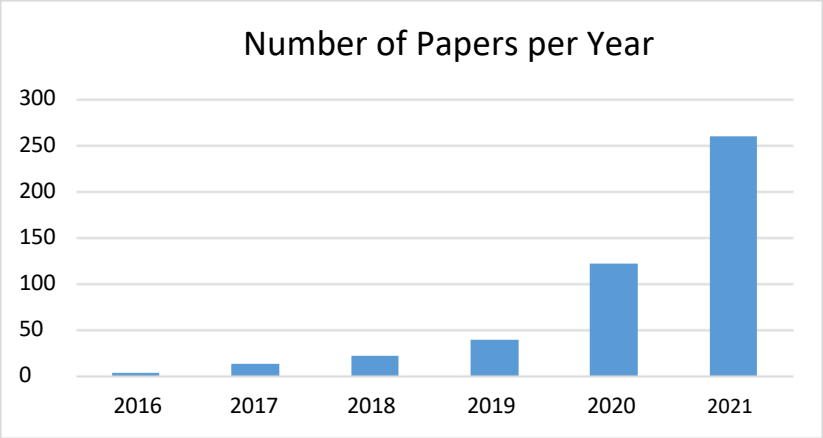

Figure 1. *Number of papers per year (source: Scopus)*

The three oldest publications date to 2016 and it is interesting to note how two of them cite CBE in the title. To better understand the yearly trends of published papers on CBE, we can ideally divide the information into two periods of three-year extension, 2016-2018 and 2019-2021. Between 2016 and 2018, a total of 38 peer-reviewed paper has been published, just one unit less than in 2019 alone. Instead, between 2019 and 2021, the total number of publications amounts to 420. This means that the last period represents 91.72 % of the considered production compared with 8.28 % of the first period. Although excluded from the survey, quick research shows that 2022 follows the growth trend and is expected to be the most productive year for the sector so far. However, the short period of time covered by the Elviser scientific search engine confirms that we are confronting just the early stages of an extremely recent scientific field whose full potential requires to be adequately explored.

The increasing attention paid to the topic in the academic literature is also demonstrated by the considerable number of citations reached by the sample at the time of the research: 6833 total citations with an average of 14,9 citations per publication. A number that knows a high rate of increase, as attested by the statistics provided by SciVal.

The analysis of the sources reveals that the 458 collected papers have been published in a total of 159 journals, but only nine of them have 7 or more publications collecting nearly 37% of the results. In addition, as it can be observed by reading the following table, top journals seem to have a strong focus on subjects that can be considered closer to the Bio-technology and Bio-resources discourses of BE, i.e.: technologies applied to bioresource, production of energy, sustainable chemistry and engineering.

Table 2. *Journals with seven or more publications (source: SciVal)*

Journal	Number of Papers
Bioresource Technology	47
Journal of Cleaner Production	30
Sustainability	29
Journal of Environmental Management	14
Renewable and Sustainable Energy Reviews	14
Energies	12
ACS Sustainable Chemistry and Engineering	8
Science of the Total Environment	8
Forest Policy and Economics	7

The number of authors is significant with 2075 researchers that can count one (87.90% or 1824 of them) or more than one contribution (12.09 %) among the 458 articles and review. By looking at their country of affiliation it is possible to trace the geographical origin of the scientific production. The investigation shows that 81 countries are involved with India, Italy and China as the three leading ones. In this regard, figure 2 allows to notice a consistent presence of European countries, that might be explained as response to the release of two fundamental documents by the European Commission, i.e. the Updated Bioeconomy Strategy (2018) and the European Green Deal (2019) where the centrality of CBE in the sustainable transition is affirmed. Nevertheless, almost all the European Countries mentioned among the 10 most productive ones have developed a national BE strategy or a CE action plan, or both (Biancolillo et al., 2020; Duque-Acevedo CLICProject.eu). The Asian region is also well represented with three of its most advanced economies in the top 10. From this point of view, CBE seems to transcend the different geographical distribution of its two components as described in 2017 by D'Amato et al. who identified a Chinese dominance in the CE sector compared to a strong European focus on BE (D'Amato et al., 2017).

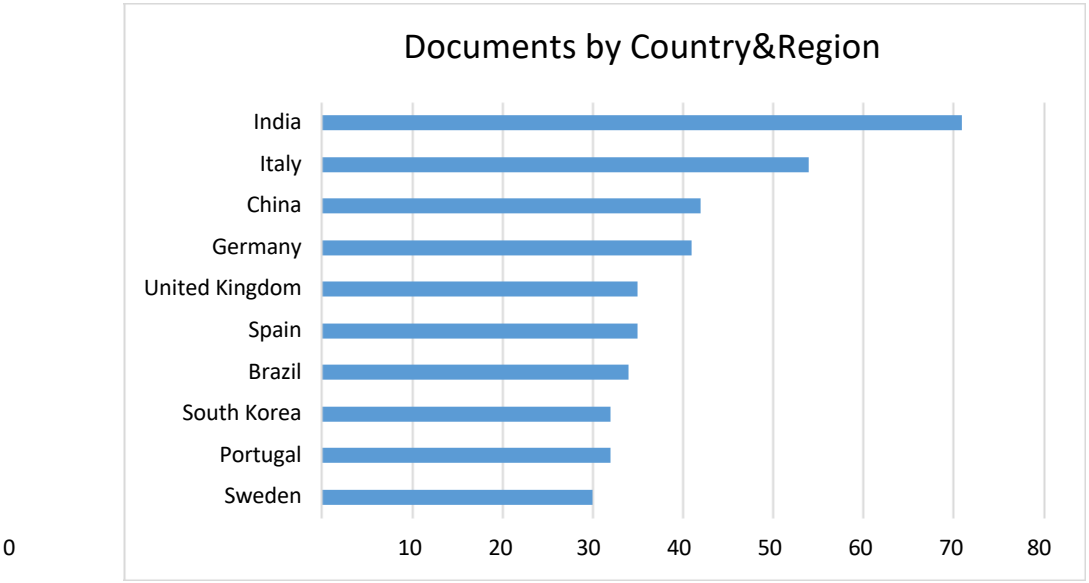

Figure 2. *Geographical origin of the scientific production (source: SciVal)*

If we add up the documents assigned to each of the 81 countries identified, we obtain a much higher number than the above-mentioned 458. This is explained by the fact that both Scopus and SciVal are influenced by the collaboration factor which implies counting the country of affiliation of each author who contributed to the publication. Indeed, in terms of collaborations, according to SciVal metrics, 201 peer reviewed papers (43.9% of the total number) are the result of international collaborations, 114 publications (24.9%) are labelled as only national collaborations, 123 works (26.9%) are classified as only institutional collaborations and just 20 outputs (4.4%) are attributed to a single author.

The strategic role of the European Union that emerges from the geographic distribution of the sample is, to some extent, confirmed by the Scopus list of the 15 main founding sponsors interesting in support the development of the topic. As can be easily deduced from Figure 3, the European Commission and research programs promoted by the European executive body itself appear as the major sponsors.

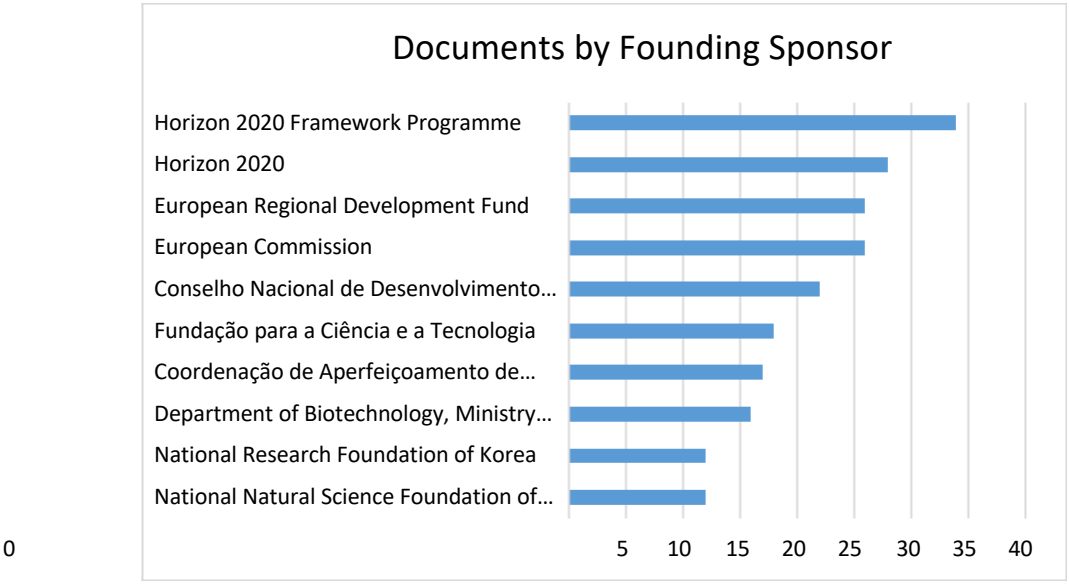

***Figure 3**. Documents by founding sponsor (source: Scopus)*

For concluding the performance analysis, could be useful to have a glance at the main subject area where CBE is discussed. According to figure 4, the 458 results fall in 25 disciplines and most of them, especially if we look at the 14 prominent ones, have a clear technical and energetic orientation. An aspect that, knowing the characteristics of the three BE Visions identified by Bugge et al. (2016), may suggests an orientation of the sample towards the Bio-Technology and the Bio-resource visions in which the technological, engineering and chemical dimensions play a decisive role in the production of bioenergy and bioproducts through the valorisation of bioresources.

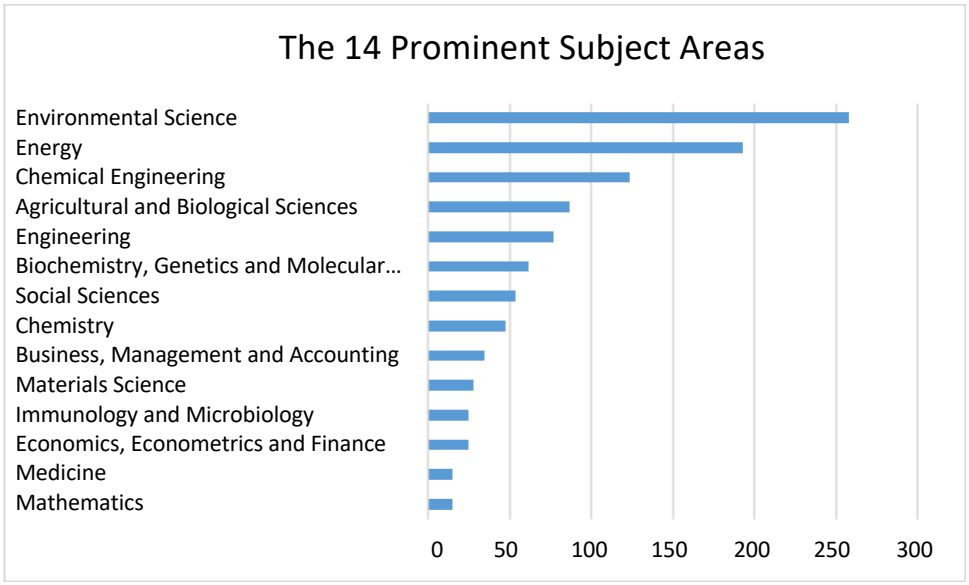

Figure 4. *Documents by Subject Area (source: SciVal)*

A deduction that appears to be supported by the analysis of the most relevant Topics addressed within each subject area, as reported in the following figure 5, results of a specific SciVal features. In particular, the Topics are represented as bubbles whose size depends on the output of the selected entity, the number of papers attributed to the topic in this case. Regarding the position of the bubbles, it is based upon the subject areas of the journals in which the document is published. This means that a topic will be brought towards the section of the Wheel of Science where the subject areas with the greatest influence on it are located. Consequently, the closer topics are to the centre of the Wheel, the more likely they are to be multidisciplinary, compared to the Topics towards the edge of the Wheel (Elsevier, 2022). And this because a paper could be related to multiple subject area, but not to more than one of the 96,000 Topics formed by SciVal.

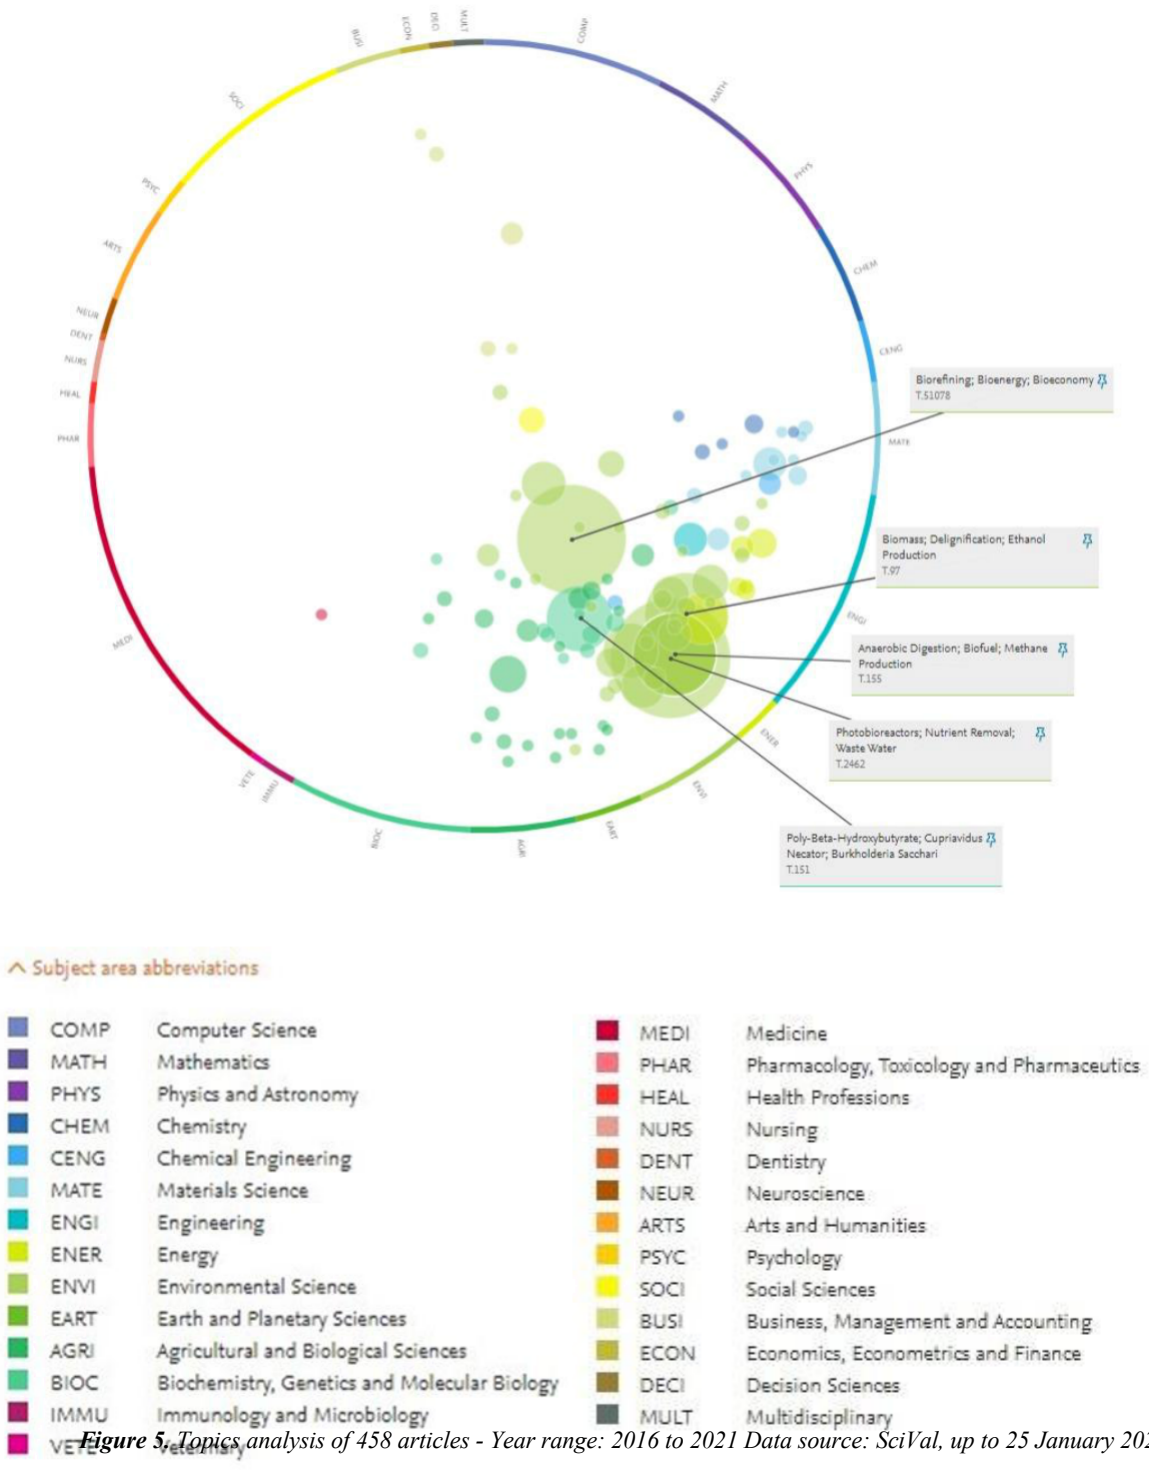

Figure 5. *Topics analysis of 458 articles - Year range: 2016 to 2021 Data source: SciVal, up to 25 January 2022*

Indeed, according to the explained figure 5, the 5 most prominent Topic for scholarity output in our sample are: 1) Photobioreactors; Nutrient Removal; Waste Water (31 documents); 2) Biorefining; Bioenergy;

Bioeconomy (28 documents); 3) Biomass; Delignification; Ethanol Production (21 documents); 4) Anaerobic Digestion; Biofuel; Methane Production (21 documents); 5) Poly-Beta-Hydroxybutyrate; Cupriavidus Necator; Burkholderia Sacchari (16 documents). They collect about a quarter of the analysed 458 papers and present an evident focus on bioresources, bioproducts, energy and biotechnologies as most of the other 171 following Topics giving significative evidence of the supposed orientation of the sample toward the Bio-technology and the Bio-resource narratives.

3.2 Science Mapping

To perform Citation Analysis and ascertain the most influential publications in a research field, we relied on the citation overview function provided by Scopus, the search engine chosen for building the sample. We decided to direct our attention to the 10 most cited peer-reviewed papers in the effort to get a first insight into the intellectual trends towards which the sector appears to be headed. The findings are summarized in the following table.

In purely quantitative terms, it is easy to observe how there is a skew in the distribution of citations with the 3 most cited papers receiving about 14% of the total amount of citations, 6883 as reported before. Obviously, this asymmetry is a direct consequence of the year of publication. In fact, citation count is known to be a measure of influence more biased toward older publication, as recent ones have less time to be cited (Župič & Čater, 2015). In line with this assertion, more than half of the papers in Table 2 date from the first three years of scientific production, 2016-2018, while the 75 units of the sample without citations have a publication range between 2020 and 2021. However, four publications, including one from 2019 and three from 2020, saw a rapid increase in citations, revealing an immediate and decisive impact on the academic community, despite their relative newness.

Table 3. *The 10 most cited papers*

Reference	Year of Publication	Number of Citations	Share of Citations
Waste biorefinery models towards sustainable circular bioeconomy: Critical review and future perspectives	2016	374	5.47
Green, circular, bio economy: A comparative analysis of sustainability avenues	2017	316	4.62
Food waste biorefinery: Sustainable strategy for circular bioeconomy	2018	239	3.50
Biorefineries in circular bioeconomy: A comprehensive review	2020	184	2.69
A Circular Bioeconomy with Biobased Products from CO2 Sequestration	2016	147	2.15
Green Bioplastics as Part of a Circular Bioeconomy	2019	111	1.62
Engineering aspects of hydrothermal pretreatment: From batch to continuous operation, scale-up and pilot reactor under biorefinery concept	2020	103	1.51
Multi-product biorefineries from lignocelluloses: A pathway to revitalisation of the sugar industry?	2017	102	1.49
The circular bioeconomy: Its elements and role in European bioeconomy clusters	2020	92	1.35
The Next Generation of Sustainable Food Packaging to Preserve Our Environment in a Circular Economy Context	2018	92	1.35

Once the counting operation has been completed, it is important to take a qualitative perspective and try to understand what information this group of influential works is able to provide concerning the thematic dynamics of the whole documents set. Already from their titles, it is possible to deduce how most of them consider the biorefinery means, the wide range of bioresources processed in them and the development of biotechnologies applied in these processes as essential elements in the implementation of CBE. A more theoretical approach to the sustainable paradigm can be read in the second and ninth paper in order of achieved references. In particular, “The circular bioeconomy: Its elements and role in European bioeconomy clusters”, authored by Stegmann et al. (2020), is the only work that attempts to elaborate a definition of the investigated narrative emphasizing the “sustainable, resource-efficient valorization of biomass”. Therefore, adopting the lens of the three visions of BE proposed by Bugge et al. (2016), we may conclude that the citation analysis seems to add another clue in support of the prevalence Bio-technology and Bio-resource topics in the collected literature.

The thematic convergence that characterizes the 10 most prominent works appears to be further confirmed by the bibliographic coupling displayed in figure 6. In this methodology, coupling strength measures the number of coupling units that two publications share, where the unit of coupling represents the shared reference (Baker, 1990). Thus, it is possible talking of bibliographic coupling network when documents in a group interrelate having at least one coupling unit in common with other members of the set (Baker, 1990). When bibliographic coupling is performed using VOSviewer, objects of interest are citing publications which are connected by lines whose thickness is determined by the number of common references. The map delivered by the bibliometric software demonstrates the existence of an interesting bibliographic coupling network among the 30 highest cited documents

which, except for two with no links, share from a minimum of 1 to a maximum of 36 units of coupling. The latter is the case of "Biorefineries in circular bioeconomy: A comprehensive review", a review published by Ubando et al. (2020) that not only boasts the third highest number of citations in the sample but also shares references with 19 of the works represented, thus forming the central light blue node of figure 6. Undoubtedly, the fact that it is a review partly explains its centrality and the inevitable link with older works from 2016-2018. However, it is also true that the work of Ubando et al. (2020) has numerous and strong relationships with contextual or subsequent publications on biorefinery concept, transition to renewable biobased energy sources and sustainable waste management. Thematic streams that can also be deduced from the network of links that unfolds from the second most interconnected publication, "Sustainable food waste management towards circular bioeconomy: Policy review, limitations and opportunities", the purple item located right above the central light blue one of Ubando et al (2020).

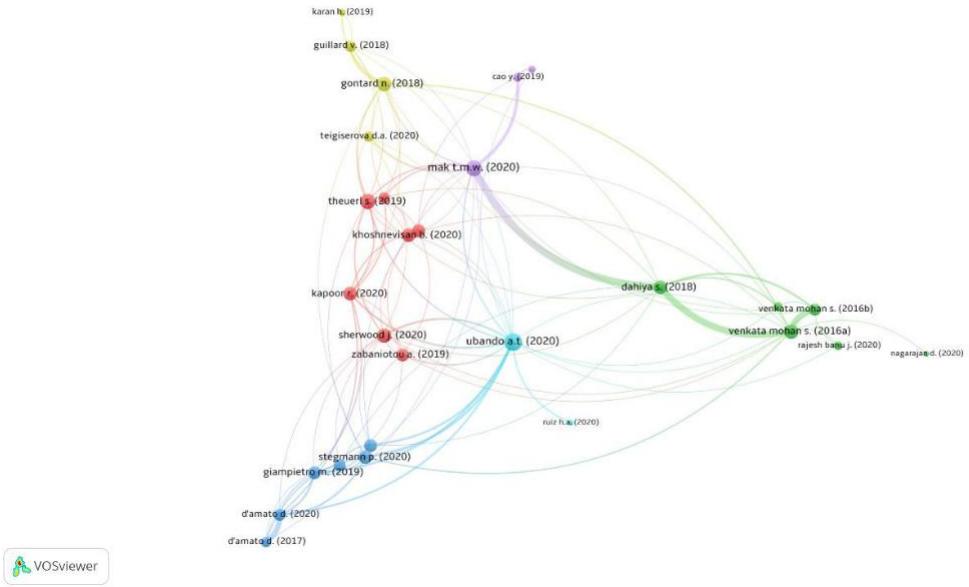

Figure 6. *Bibliographic Coupling Network Visualization of the 30 most cited papers*

However, the perception of an intense bibliographical correspondence and, therefore, of a probable thematic assonance finds a significant confirmation when the methodology in question is extended to the whole set of 458 publications projecting beyond the boundary of the 30 most cited papers. Indeed, the density diagram presented in Figure 7 reveals that the vast majority of the sample is crossed by a consistent coupling strength, especially within the broader cloud of 380 items that runs longitudinally through the centre of the map including the studies with highest bibliographic coupling scores. In this case, the density visualization function made available by VOSviewer

was chosen in order to facilitate the understanding of the geography of a map with so many elements. Through a wise use of the weight options, it has been possible to highlight the elements with the largest number of shared references and their areas of influence. Overall, 436 publications are related, albeit with different levels of intensity. The peak of 304 of shared references is reached by the work of Duque-Acevedo et al., published in 2020 and titled "Analysis of the circular economic production models and their approach in agriculture and agricultural waste biomass management". As can been seen, this second visualization is pivotal for a deeper comprehension of the theoretical foundation of the 458 contributions collected for this research. The topography of Figure 7 gives visibility to newer or niche works indicating that the presence of certain level of thematic coherence is not a prerogative of only the most cited works. Going in detail, almost 20 prominent studies respect to this type of indicator date from 2020-2021 and, except for the aforementioned review of Ubando et al. (2020), do not exceed the threshold of 70 citations.

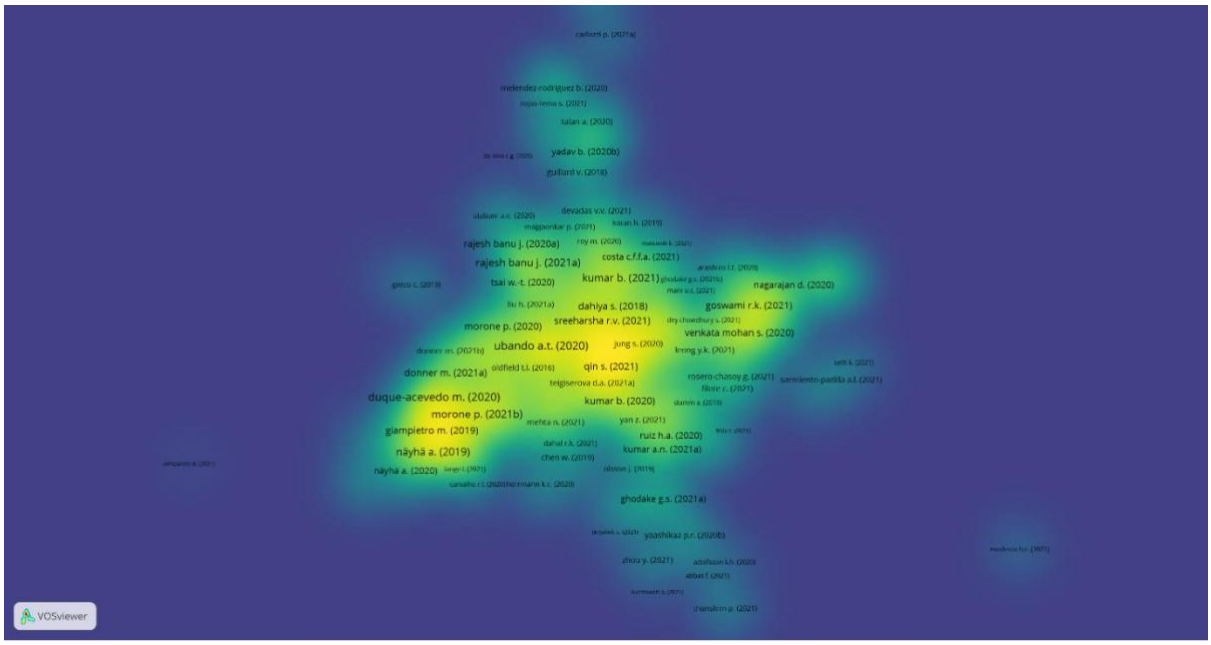

Figure 7. *Density diagram of the bibliographic coupling of 436 interconnected papers*

Finally, to retrieve a more dynamic comprehension of the distribution and relationships of BE visions in the sample a Co-word analysis has been carried out by screening the content of both titles and abstracts. A technical choice designed to compensate the problem that could derived from relaying on just one category of text data. In particular, when dealing with titles or keywords, the so-called "indexer effect" should be taken into account, because not always these indexers are able to reflect all relevant aspects of an entire document. On the contrary, the use of abstracts as well as full texts can bring disturbance complicating the identification of important words (Župič &

Čater, 2015). Consequently, exploiting the versatility of VOSviewer, a network map of co-occurrence links between terms has been built using text data extrapolated from both titles and abstracts (VOSviewer Manual).

The titles words network map generated by VOSviewer is represented in Figure 8 and includes, out of a total of 1577 analysed words, only terms with a minimum number of 5 occurrences. Since the size of the circles is proportional to their weight, words with a higher occurrence are shown more prominently than word with a lower occurrence. If two words appear together, they are connected by links whose thicknesses explains the extent of their occurrence relationship (Kim et al., 2016), i.e. the number of titles in which the two keywords were used together. The 45 words that meets the occurrence threshold are grouped in 6 clusters of differ colours. The clusters, whose number is determined by the resolution parameter, are highly interconnected. This aspect makes hard to isolate a main topic inside each cluster, but, at the same time, may be regarded as an indirect confirmation of the multifaceted and complex nature of the subject matter. However, since VOSviewer takes a distance-based approach to visualizing bibliometric networks, the distance between two items is also determinant for the correct interpretation of the map, because it is symptomatic of their degree of relatedness: in general, the closer the nodes are, the stronger their relationship is (Van Eck & Waltman, 2014). In this regard, the proximity, or rather the overlap, between the CBE and biorefinery items, both belonging to Cluster 5 (in purple), is quite evident indicating the key role assigned in the examined literature to this typology of multi-output production chain in the implementation of CBE (Stegmann et al., 2020). From a holistic point of view, this first stage of the co-word analysis, synthesised in the structure of Figure 8, supports a preponderance of terminology associated with the Bio-resource and Bio-technology visions. The articulation of the titles seems to describe CBE as production-oriented concept, a future perspective of development that see an opportunity of transition in the valorisation of bio-waste and in its conversion into a wide range of products mainly through the application of new advanced biorefinery technologies. The robust connections between CBE and items such as production, waste, valorisation and, once again, biorefinery clearly move in this direction. On the other hand, the lack of terms related to the Bio-ecology discourse is eloquent. Indeed, the sustainability node has a marginal relevance as witnessed by its relatively low number of occurrences compared to words typical of the other two visions of BE. The ties with strategy and life cycle assessment show that the sustainable dimension is included and addressed in the sample even if probably not in the strong sense promoted by the third vision of BE. In addition, it is interesting to notice how in Figure 8 the string “sustainable circular bioeconomy” is a stand-alone element with an occurrence of 10. A detail that could be subject to a double reading: on the one hand it could compensate for the lack of a direct link between CBE and sustainability, on the other hand it could reveal a tendency to interpret CBE concept as sustainable per se.

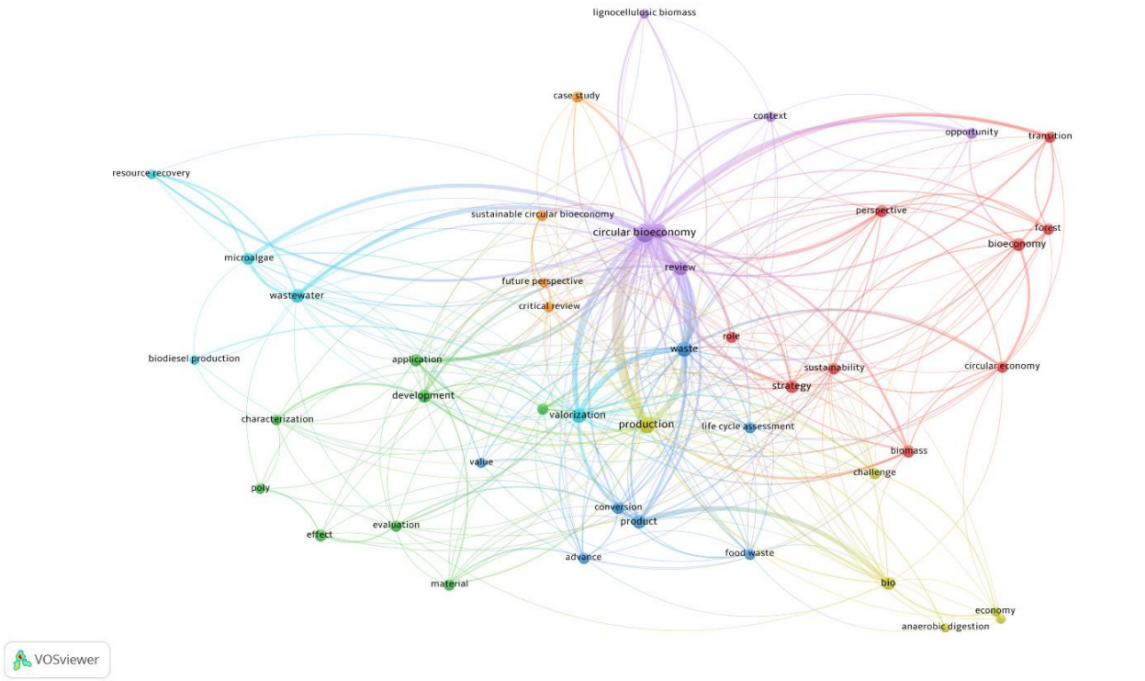

Figure 8. *Titles words network map*

Figure 9 documents the second stage of co-word analysis by extracting from the abstracts the terms with a minimum occurrence of 20. In this case, VOSviewer produces a network map of 125 objects divided into 4 clusters with a considerable level of interactions. Despite the inevitable noise introduced using large corpuses of text, extending the co-word approach to the abstracts proves to be an effective way of pursuing quality through quantitative (Callon et al., 1986d). Without affecting heterogeneity of the investigated scientific field, it has been possible to recognize and graphically aggregate some conceptual features that can corroborate previous results and, at the same time, highlight details that deserve to be further investigated. As in Figure 8, while CBE maintains a relatively central position in the map, we can also appreciate an increased plethora of technical expressions mainly linked to the production item located in the red cluster. In continuity with the previous phase of the analysis, the lack of terms related to the social and environmental dimension is still manifest. Although, this time, there is a direct connection between CBE and sustainability, the distance between these two nodes suggests a limited impact of latter one on the former one. A similar observation can be directed towards other objects such as environmental impact, climate change and sustainable development whose peripherical position, as well as their network of links, has significant implications in describing the cognitive structure of the sample. As epitome of the research path proposed in this study, the co-word analysis of abstracts depicts a notion of CBE characterized by a macro focus on bio-resources and their capitalisation into a wide spectrum of new marketable products, in particular energy, through the application and commercialisation of advanced technologies. Zooming on the map, the principal evidence in favour of this conclusion can be found in the area, to the left of the CBE node, occupied by the self-explanatory subnetwork

composed of production, waste, process, biomass and technology. As the swich to density visualisation shown in Figure 10 can easily demonstrate, this is the area that reaches the highest level of both occurrences and total link strength, where the total link strength measures the total strength of the co-occurrence link between terms (VOSviewer Manual). A quantitative and graphic aspect that, according to the assumptions of co-word analysis, allows to perceive this combination of words as an influential pole in the thematic architecture of the sample. Undoubtedly, both the technological and ecological-environmental components are taken into account, but in a sense that might be considered distant from that promoted by the respective visions of reference, i.e. Bio-technology and Bio-ecology visions. The network geography seems to indicate a prevalent preordination of technological research and development to the improvement of processing and conversion of biological raw materials, in coherence with the idea of technology innovation highlighted in the Bio-resource vision. Indeed, as well as Bio-technology vision, the Bio-resource vision emphasises the importance of research and innovation as driver of value creation, but in a less linear way that transcends the narrow science application of technologies calling for stronger cross-sectoral collaborations in multiple fields related to biological materials (Bugge et al., 2016). Similarly, the sample appears inspired by a meaning of sustainability as a consequence of bio-innovation and bioresource capitalization, and thus far from the strong connotation adopted by the Bio-resource vision.

Always in the light of Bio-resource principles, should be read the conspicuous presence of terms borrowed from the waste sector. In this regard, the high co-occurrence strength between waste and biorefinery items, in both titles and abstracts analysis, requires attention because it might be implied that the energy production from bio-waste plays a key role in CBE literature and is not intended as the extrema ratio recommended by the Bio-ecology narrative.

In conclusion, trying to interpret the results of the different science mapping techniques in a unified way, the following answer to the research question emerges: the new research field of CBE present a common thematic foundation that seems to be mainly inspired by a bio-resource vision of BE and grounded in a weak sustainability narrative. An answer that leads the consideration that CBE, as its building blocks, is a resource focused paradigm (D'Amato et al. 2017) that is still missing a preponderant social and environmental dimension and is unable to offer a solution to the sustainability challenges posed by BE and CE.

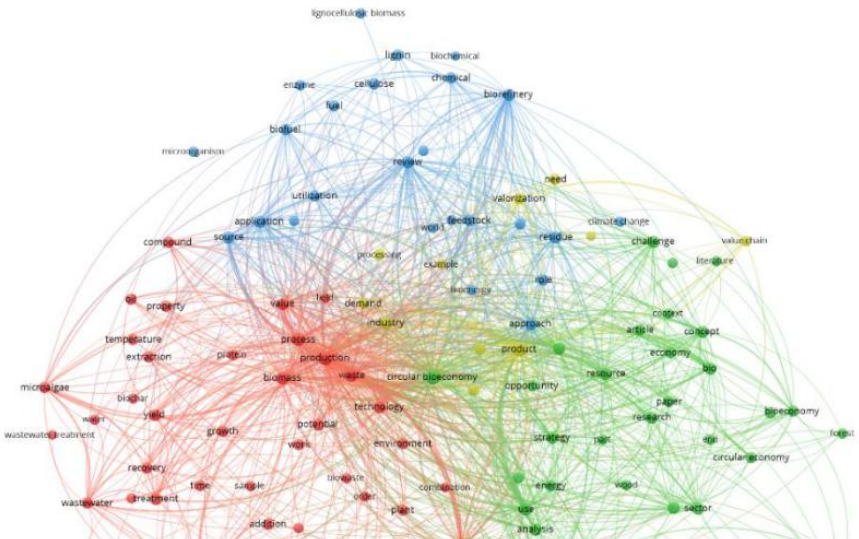

Figure 9. *Abstracts words network map*

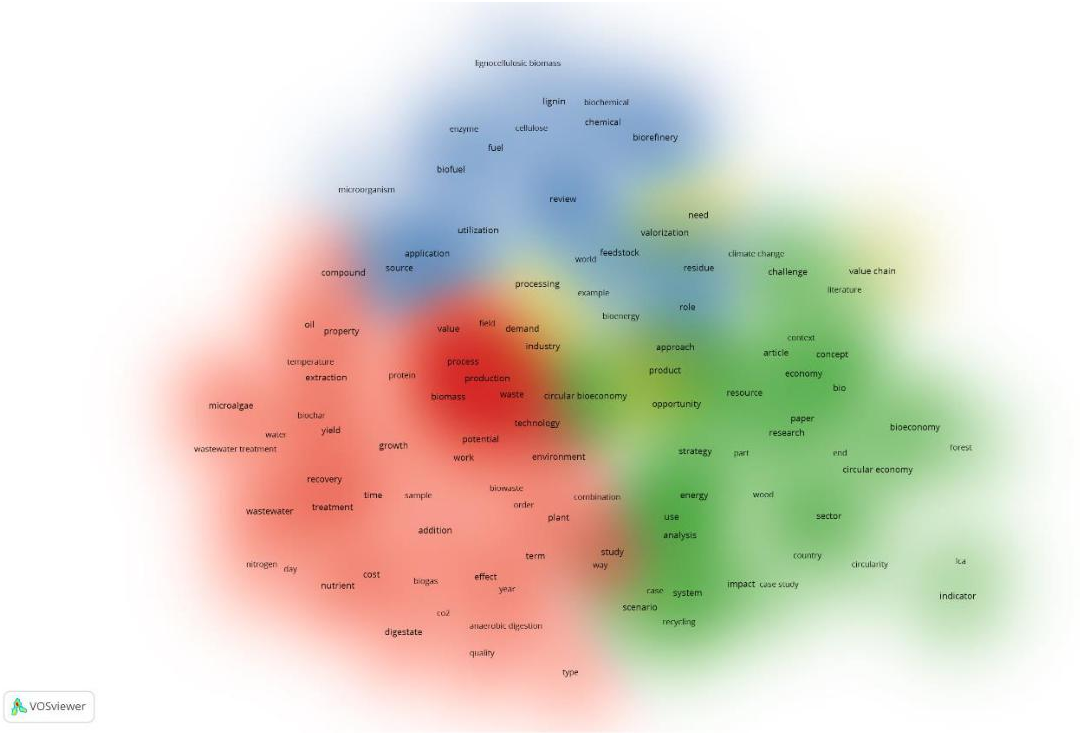

Figure 10. *Density visualisation of abstracts co-word analysis*

4. Conclusions

Through an articulated methodological structure, the present study has aimed to deepen the recent concept of CBE trying to provide a first response to the theoretical challenges posed by its extremely controversial and nebulous nature. To contribute to define more accurately the epistemological boundaries of the phenomenon, we proposed a hermeneutic pathway that focuses on the analysis of one of its constitutive components, the BE. A detailed bibliometric analysis was conducted, employing several advanced bibliometric tools, and the results were interpreted according to the taxonomy developed by Bugge et al. (2016) in order to understand which view of BE could be considered prevalent in the CBE landscape.

The performance analysis confirms, firstly, that CBE is gaining increasing attention in the literature, being recognised as innovative sustainable solution in a yearly growing number of papers mostly authored by researchers affiliated to European and Asian institutions. A possible intuition of the BE visions towards which the sample may be oriented begins to emerge when dwelling on the top journals active in the sector as well as the subject areas and topics to which the collected publications are attributed.

However, thanks to science mapping techniques it is possible to outline, at least from the macro perspective typical of this methodology, a more elaborate answer to the research question. If the bibliographic coupling

suggests a certain degree of thematic similarity within the considered sample, the co-word analysis, as content approach, allows to identify and visualise the direction of the intuited conceptual convergences. In fact, even if the difference should not be considered in a strict way and the three BE discourses necessarily interrelate on different levels (Bugge et al., 2016), there are consistent evidence of an alignment of CBE with the terminology associated with the Bio-resource vision. The technological aspect of the first vision is also covered, but always in a way that is instrumental to understand how and which resources to employ efficiently. Overall, it is possible to perceive an under-representation of the themes specific to the Bio-ecology visions.

Although this is a preliminary and exploratory study, it provides results that will be pivotal in orienting the future phase of the research on CBE. Indeed, even with its inevitable methodological limitations, the proposed contribution allows to highlight how CBE is still an evolving notion whose understanding requires further investigations if we intend exploit its full potential as solution for the present and future environmental, social and economic challenges.

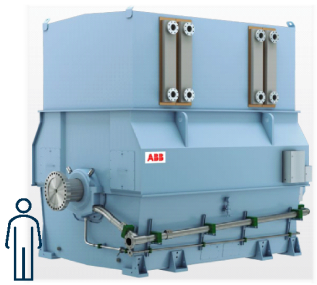
For durable and energy intensive products, maintaining high energy efficiency is key for repair to be beneficial

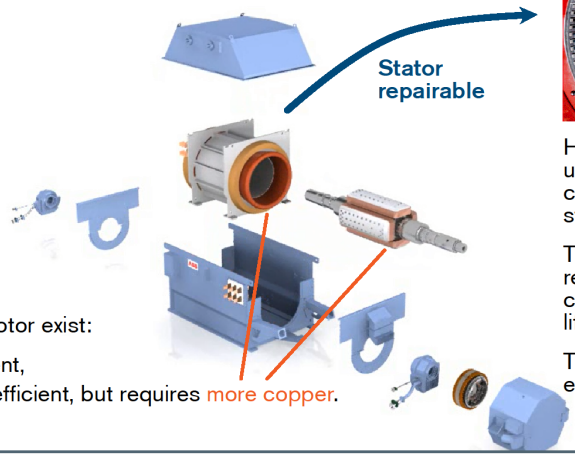
Adeline Jerome, Maria Ljunggren and Matty Janssen

For **durable and energy intensive products**, maintaining **high energy efficiency is key for repair** to be beneficial.

Context

High voltage electric motors are big and long-lived (designed for min 20 years) stationary motors used in the industry. Examples of application are in the chemical and metal industries, to drive pumps or compressors.





Two main designs of high voltage motor exist:

- Induction motor: less energy efficient,
- Synchronous motor: more energy efficient, but requires more copper.

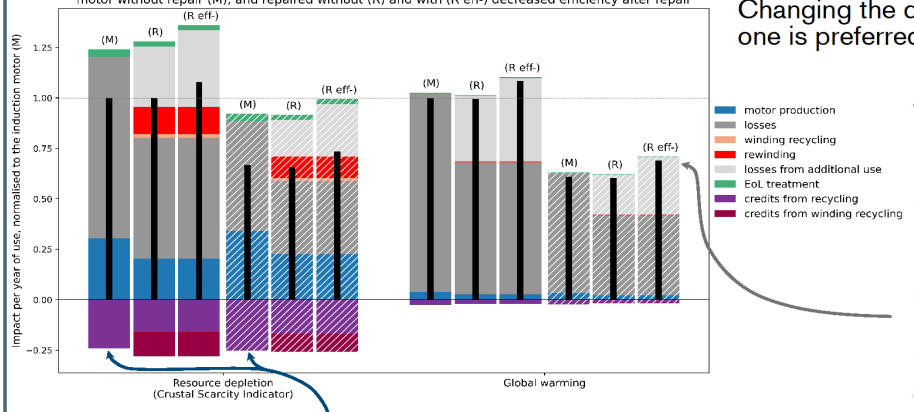
High voltage motors are often used until failure, with one of the most common faults occurring in the stator copper windings.

The stator could be repaired by rewinding, i.e. replacing the copper windings, for an additional lifetime (here assumed 10 years).

The repair may lead to a reduced energy efficiency.

Results

Comparison of the environmental impact for the induction (non-hatched) and synchronous (hatched) motor without repair (M), and repaired without (R) and with (R eff-) decreased efficiency after repair



Higher production impact on resource depletion for the synchronous motor. But lower energy losses compensate for the difference.

Changing the design to a more energy efficient one is preferred over use extension with repair.

The contribution of rewinding is lower than motor production.

But the net benefit of repair is very small for both global warming and resource depletion (comparison of (R) and (M) for both designs).

With an efficiency reduction after repair, the additional energy losses offset the gain from avoiding the production of a new motor (impact for (R eff-) higher than for (M)).

The repair is not beneficial if high efficiency is not maintained.

Environmental sustainability of high voltage motors: do better efficiency and repair lead to improved environmental impact?

Abstracts

The Food Retail Sector towards a Circular Economy

Dr Carmen Jaca, Dr Marta Ormazabal, Dr Maria Jesús Alvarez-Arjona, Florencia Kalemkerian

Tecnun- Universidad de Navarra, San Sebastian, Spain

Abstract

Retailing is a key activity for cities as it helps to meet citizens' needs and generate economic activity. This activity refers to the sale of goods or services from manufacturers and producers to individual end-consumers and consequently, retailing consists of the last step in a supply chain including the sale of a product or the provision of a service to the final consumer.

In the current context, where cities need to accelerate their transition to a circular and sustainable economy, retailers are an important agent of change. They can adopt sustainable practices in their own internal processes and also facilitate the adoption of sustainable behavior among their customers (Paiho et al., 2020). Although retailers can contribute significantly to the implementation of a circular economy, little attention has been paid to this field of research in the literature (Wautelet, 2018). It is therefore crucial to better understand their role and how they can potentially accelerate the transition to a circular economy.

The objective of this research is to work with a group of people representative of different profiles of this sector to have a diagnosis and in turn, constitute a first group of traders involved in direct actions in their business. This research project consisted of four workshops aimed at traditional businesses in the food retail sector located in San Sebastian, in northern Spain. Specifically, the food sector has been selected, as it is one of the key sectors in the European Green Deal and as it accounts for 30.7% of the city's businesses. The workshops were as follows:

- What is my value proposition? Customer of the 21st century
- How can I be more sustainable? Business sustainability
- How can I get more out of my waste? Waste: waste or business?
- How can you help me in this improvement of the circular economy? Conclusions

In each session, an introduction to the concepts related to the topic and good practices was given. Then, through participatory dynamics, exercises were carried out to reflect on their businesses in order to analyze their processes and think about improvements and opportunities.

An interesting atmosphere was created in which new ideas emerged, relevant problems were pointed out and experiences were exchanged. Those attending the workshops were people who were environmentally aware and motivated to improve in this regard. One opportunity that arose from these workshops is the need to collaborate among them and with other agents to address actions that would not be possible on their own.

Applying Oiconomy Pricing

First experiences of producers applying real cost sustainability assessment of products

Vermeulen, W.J.V.[1], Croes, P.R. [2], van der Feen, L.[3]

Abstract

The Oiconomy approach provides a normalized way of measuring and communication of (un)sustainability. In this standard (un)sustainability is expressed in a virtual monetary unit, the "ESCU" (Eco Social Cost Unit). As closely as possible, the ESCU score of a product equals the hidden preventative costs, or externalities, related to a product, the costs that should have been spent to avoid any of the damage that the product causes during its entire lifecycle. This assessment addresses preventative costs for all UN-SDG sustainability aspects including Planet-aspects (climate impacts, biodiversity, land use, resource depletion, circularity), People-aspects (working conditions, fair wages, health), and Prosperity-aspects (corruption, fair inequality, fair trading). Added to the standard economic price of the product the ESCU score represents the total costs of a fully sustainable alternative for the product. The ESCU also provides a normalized means of transfer of (un)sustainability through the supply chain enabling all players in the supply chain to build on each other's data.

This paper presents the result of a pilot project with three companies, operating in global value chain, applying the Oiconomy Sustainability Assessment Tool.

Goals of the Oiconomy Project are to develop a uniform and aggregable measurement of the preventative cost distance to sustainability for products. With this it aims to make 'preventative costs' a permanent topic in the supplier – customer communications. The project encourages end-producer companies and their whole value chains to calculate and implement sustainable solutions. The tool provides an innovative comprehensive measurement of environmental sustainability and social responsibility.

In a pilot project three Dutch end-producer companies (one selling spices to consumers, one producing kitchen topping and one producing medical devices) applied the new methodology together with their suppliers, partly in low-income countries (Indonesia, Ukraine, Egypt). The goal of the pilot study was to test whether the tool was clear enough to be applied by company experts instead of external consultants, to identify points of improvement before further market introduction and share experiences which forms of presentation of the

outcomes in the supplier – customer communications and evoke collaboration about further performance improvement. The methodology has so far been described in various scientific articles in the International Journal of Life Cycle Assessment and the Journal of Cleaner Production, yet without real life testing.

In the paper we will show the results of these calculations for the three cases, the experiences of the companies and the implications for the market introduction of the tool.

Keywords: True Cost Accounting, Life Cycle Assessment, Sustainable Value Chain Management, Corporate Sustainability

1. Introduction

Corporate sustainability (CS), also described as corporate social responsibility (CSR, MVO), presents the role of the business world in contributing to the full complexity of the current massive sustainability challenges. This problematic complexity is illustrated by the 17 Sustainable Development Goals (and 169 sub-goals) agreed upon in the United Nations. It includes a twin agenda of integral environmental and societal fairness: the triple-P agenda (Planet, People, Prosperity) (Vermeulen, 2018). The World Business Council of Sustainable Development (WBCSD) argues that this critical agenda cannot be realized without effective engagement by the private sector. As a crucial element of their programs for business engagement they state that "better information equals better decision-making; disclosing sustainability risks and impacts, and pricing them appropriately, is increasingly where the market is heading for" (WBCSD, 2022).

However, the practice of corporate sustainability performance measurement rather still looks like the Babylonian confusion of speech. First problem is that many competing measurement tools exist, mostly addressing only a few or one of the 17 SDGs, not integrating the environmental and social dimension. Second, these tools focus on measuring the negative impacts produced, thus not showing companies what they could or should do, but rather blaming and shaming them. Third, many of these assessment tools are based on general available data on negative impacts for product categories, provided by tools and repositories, like Ecoinvent, Gabi and Simapro, using national averages. Thus, companies cannot fully show the own specific improved performance compared to competitors. The assessment of both the environment and social performance cannot yet be appropriately integrated in one consistent comprehensive system.

As a solution for these needs the Oiconomy Pricing methodology was developed. It presents a practical tool for companies which enables them to make a full triple-P spectrum assessment together with their main suppliers, in the standard monetary language in the market, which a focus on solutions (prevention options), rather than on negative impacts on nature and society. Some forms of monetary approaches in product assessment do exist at this moment (like TruePrice), however the transparent, non-profit, science-based

approach and the focus on prevention instead of damage costs are unique in the world, as well as the feature that companies apply the methodology themselves and can integrate that in their supplier base information systems.

2. Methods

The Oiconomy Pricing methodology has been developed in the PhD research of dr. Pim Croes, who defended his PhD thesis (Croes, 2021) on January 14th, 2021. The research focussed on positioning the core idea of the approach in the existing field of life cycle assessment and sustainability performance measurement (Croes and Vermeulen, 2015), justifying the methodological ground rules. The methodology for establishing default values, applied when companies do not have the company specific preventative cost information themselves, was elaborated with state-of -the art reviews and check on data quality of existing global databases for examples of social impact indicators, including fair wages, levels of inequality and corruption prevention (Croes and Vermeulen, 2016a, 2016b, 2019). The methodology includes a systematic analysis of methods used for including positive impacts in the methodology, preventing forms of greenwashing in this respect (Croes and Vermeulen, 2020). This scientific groundwork resulted in 5 articles published in the Journal of Cleaner Production and the International Journal of Life Cycle Assessment.

The negative hidden costs measured in Oiconomy Pricing are covering all 17 UN SDGs and all triple-P pillars (Planet, People, Prosperity). Table 1 displays the included aspects in measuring the preventative costs towards a fully sustainable product. In contrast to many environmental assessment methods, Oiconomy Pricing addresses all SGD related sustainability aspects in a consistent and comprehensive methodology. It enables fully integrated assessment and prevents (unintended) trade-offs between sustainability aspects. All prevention costs are expressed in a virtual monetary unit, the “ESCU” (Eco Social Cost Unit). This represents the costs that should have been spent to avoid any of the damage that the product causes during its entire lifecycle and can be transferred into any currency. Besides negative hidden costs, positive externalities, a positive externality occurs when a third-party benefits from activities or consumption of a product without contributing to the (full) costs of the transaction (Benoît Norris et al., 2009). Croes & Vermeulen (2020) formulated a list of criteria for the allocation of positive costs.

Table 1. Included aspects Oiconomy Pricing

Pillar	**Aspect**	**Measures prevention costs towards:**
Planet	Emission of toxic gasses	Zero emissions of harmful gasses/substances to air, soil and water (bulk gasses, toxic emissions and agri-chemicals)
	Use of scarce resources	Use of renewable resources instead of virgin (scarce) resources
	Biodiversity	Preservation of (original) biodiversity
	Land use	Optimizing yields for food production
	Waste & Disposal	Sustainable disposal of waste and optimized lifetime of product
People	Human health risk	Reduced human health risks
	Labour	Fair remuneration & safe labour conditions
		Fair inequality between lowest and highest salary within company
		Sufficient contribution to health insurance, personal development, and pension plans
		Ensuring occupational health & safety
		Mitigation of child labour.
Prosperity	Economic Responsibility	Fair payment to suppliers
		Responsible financial management
	Corruption & Conflict	Prevention of corruption & conflict

The system copies the normal economic price build-up in the supply chain for the hidden costs of preventing environmental, social and economic harm, inflicted as consequence of the production, use and disposal of the

product. The actors themselves make the assessments and calculations and transfer the results to the next in the supply chain. When self-provided ("foreground") data are not available,

the system provides default ("background") data. There are two types of data used in the system 1) performance data and 2) data on prevention costs. Performance data is data measuring the sustainability performance of companies (e.g. kWh used). Performance data should be foreground data as much as possible, as this reflects the reality of activities in the supply-chain. Data on prevention costs reflects data on the cost of sustainability mitigation measures (e.g. investing in solar panels). It is preferable to use company-specific prevention costs, however this takes time as companies need to assess the costs of specific mitigation measures. If such data is unavailable, generic data-base sourced data on sustainability mitigation measures are used.

Trustworthiness of the data is obtained by verification and certification according to international standards. A draft standard is available for certification purposes and an assessment tool for the actors in the supply chain.

The core design principles of the Oiconomy system of the approach are:

1. All triple-P pillars (Planet, People, Prosperity) are included, covering all 17 UN SDGs. The word "sustainability" therefore includes social and economic responsibility.
2. (Un)sustainability is determined by the additional costs for a sustainable product version, expressed in "Eco Social Cost Units" (ESCU's).
3. ESCU's are transferred as one total value, but also separately for the 10 aspect categories.
4. Verification of the reliability of the data takes place by means of certification on the Oiconomy standard (in the future).
5. Information about the sustainability performance in the form of ESCU's is transferred and documented in the value chain like normal prices (without the margins). The Oiconomy System is a bookkeeping system for the yet hidden preventative externalities.
6. By only transferring information in the form of aggregated ESCU's, intellectual property of production specifications of suppliers remains safe.
7. The Oiconomy system is a type of "Life Cycle Assessment", but measured by the value chain actors themselves, instead of afterwards by scientists, consultants or NGOs based on general databases.
8. Without demonstrable specific data, generic default values from a database are used, but the companies can continuously improve these with their specific data and investment calculations.

To apply Oiconomy pricing, the Oiconomy Sustainability Assessment Tool has been developed. It leads the practitioner through all stages of the product life cycle and along all aspects of sustainability. By means of a questionnaire, all aspects of sustainability are measured, and the hidden cost are automatically calculated. Figure 1 displays the process of calculation hidden costs through the Oiconomy Assessment Tool. The first step in applying the assessment is scoping of the supply chain. The practitioner needs to identify suppliers that are within 80% of the purchased value of a product. The suppliers that fall within the 80% scope needs to be

included in the Oiconomy Pricing Assessment. The tool then challenges selected companies to self-provide their specific ("foreground") costs to prevent causing harm, or in other words the extra costs (without margin) for the sustainable version of the product. However, in absence of foreground prevention costs, the tool provides default ("background") data, which are based on either internationally determined conventions, science, or benchmarks.

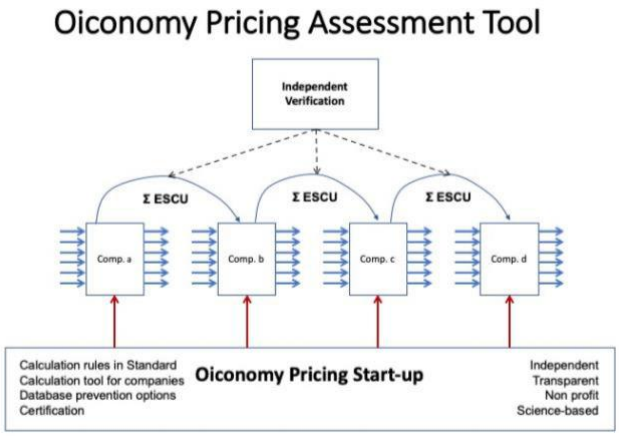

Figure 1. Oiconomy Pricing Assessment Tool

From November 2021 to March 2022, three pilot companies applied the Oiconomy Pricing, with one part-time researcher at UU available for explanations and support. The end-producers (one selling spices to consumers, one producing stone kitchen topping and one producing medical devices) involved their main suppliers to measure their hidden costs. The goal was to test whether the tool was clear enough to be applied by company experts instead of external consultants, to identify points of improvement before further market introduction and share experiences which forms of presentation of the outcomes in the supplier – customer communications and evoke collaboration about further performance improvement.

3. Results and Discussion

3.1 Case study 1: stone kitchen countertop

The first case under assessment was a company called Arte, that produces stone kitchen counter topping. The company is located in the Netherlands and produces various types of stone kitchen counter tops. The unit under review is 1 m^2 of stone kitchen countertop and the exact product properties are not disclosed due to confidentiality of supply-chain partners. The supply-chain of the stone countertop was traced back by including 80% of the purchased value. This identified the most relevant supply-chains for stone: Feldspar,

Clay and other chemicals (Figure 2). The stone surfaces manufacturer and Arte supplied foreground data and the clay, feldspar and chemical suppliers were assessed using background data from databases. The results reveal that the total hidden costs of 1 m^2 of stone countertop is € 32,44 (Figure 3). The sales price of 1 m2 stone countertop is € 912 meaning the hidden costs are adding 3,56% onto the sales price.

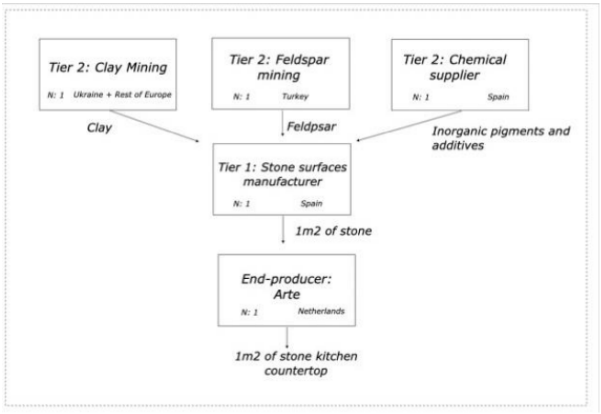

Figure 2. Scope of assessment

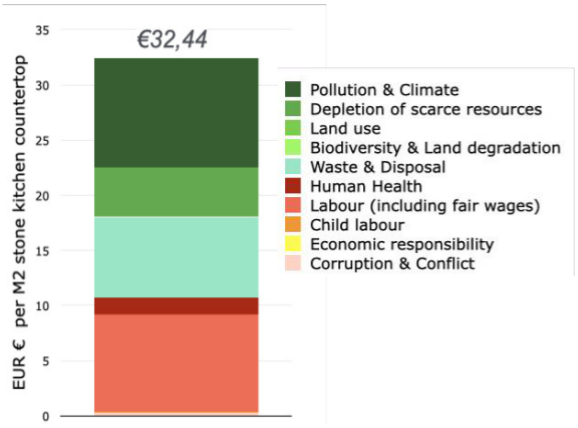

Figure 3. Breakdown negative hidden costs

The main negative hidden costs come from the category Pollution & Climate. Pollution & Climate measures the cost to prevent polluting emissions to soil, air and water. Most of the costs come from the manufacturing process and transport of the stone surfaces producer (€ 5,15), other costs include the energy usage of Arte (€ 1,54) and the mining operations of clay and feldspar (€ 2,41 and € 0,85). The second biggest category is Labour. Labour measures fair wages, fair inequality and other labour conditions. The bulk of the costs come form the stone surfaces manufacturer in Spain as they could not demonstrate the absence of various labour aspects.

There is a high risk of child labour in the feldspar and clay mines in Ukraine and Turkey. The lack of demonstrated evidence of the absence of child labour led to the allocation of €0,12. € 0,12 is the amount necessary to replace the children with adults earning the fair minimum wage. In the category Waste & Disposal, the cost- distance to sustainable disposal is measured for both processing-waste and end-of life waste. Negative costs emerge from the end-of- life disposal as the demolition of the countertop creates inert waste (€ 4,20). Furthermore, hidden costs found include cost to prevent the depletion of scarce resources. The stone surfaces manufacturer uses a lot of fossil resources, that lead to negative costs of € 1,33. Additionally, the water consumption for 1 m^2 of countertop is 0,17 m^3 and is extracted in a water-scarce area, which leads to negative hidden costs of € 3,09.

Besides negative hidden costs, positive costs were calculated (Figure 4). Positive costs of € 6,89 were found, which was spent by Arte and by the stone surfaces manufacturer. Among other things, Arte invested in extra preventative medical care for their employees (category: Social Responsibility), and set up the Responsible Stone Foundation that aims to eradicate child labour in the communities nearby stone quarries by supporting quality education (category: Economic Responsibility).

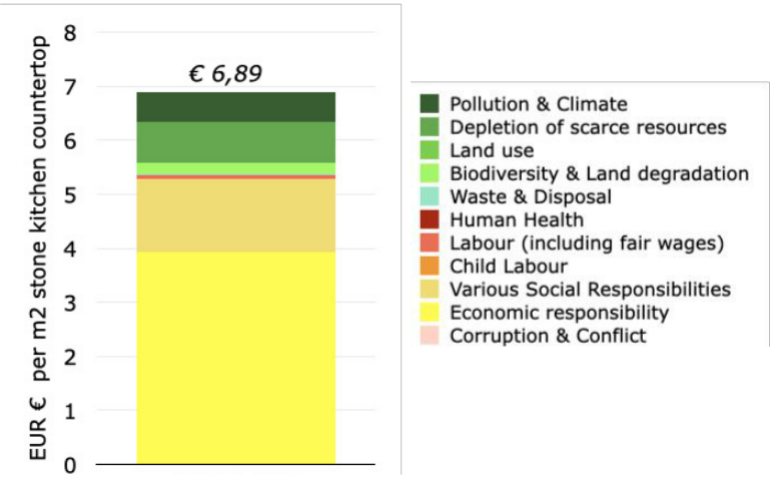

Figure 4. Breakdown of positive costs per m^2 stone countertop

3.1.1 Data specificity assessment of m^2 stone kitchen countertop

Performance data is data measuring the sustainability performance of companies (e.g. kWh used). The data specificity of performance data of this analysis is displayed in Figure 5. Arte was able to complete the assessment using mainly company-specific data. The stone surfaces manufacturer also actively took part in this pilot but was not able to demonstrate all the data, so partly, background data was used. Regarding the feldspar and clay supplier only background data was used.

Prevention costs are data on the costs of sustainability mitigation measures (e.g. investing in solar panels). The data specificity of prevention costs of this analysis are displayed in Figure 6. None of the value-chain partners were able to provide much foreground prevention costs, as it takes time to make investment proposals to mitigate impact. This should be a focus when the assessment is repeated.

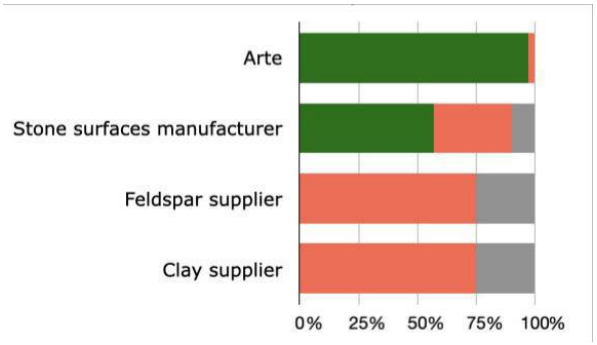

Figure 5. Data specificity of performance costs

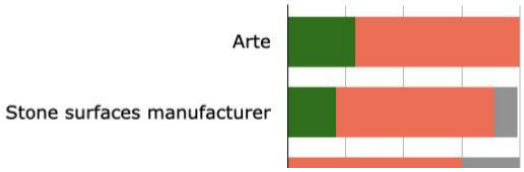

Figure 6. Data specificity of prevention costs

3.2 Case study 2: Medical Device

The second company under assessment was a company called ADMC Group, located in the Netherlands. ADMC produces medical equipment in the rehabilitation and physiotherapy field. The product under review is a pack heater. The pack heater is an electrical box that can heat packs used in heat therapy. The supply-chain of the pack heater was traced back by including 80% of the purchased value. This identified the most relevant supply-chain: the steel components (outer-body of the pack heater, inner body, the net, the cover and the handle) (Figure 7). ADMC and the steel workshops were able to provide data on their sustainability performance and data from the steel producer and steel trader was sourced using databases. The total hidden cost of a pack heater is € 130,12 (Figure 8). The sales price of a pack heater is € 1600, meaning the hidden costs are adding 8,13% onto the sales price.

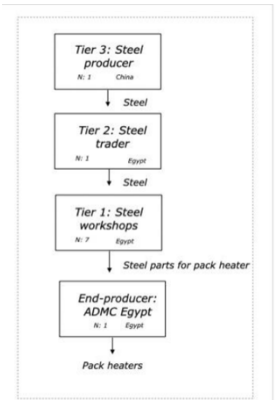

Figure 7. Scope of assessment

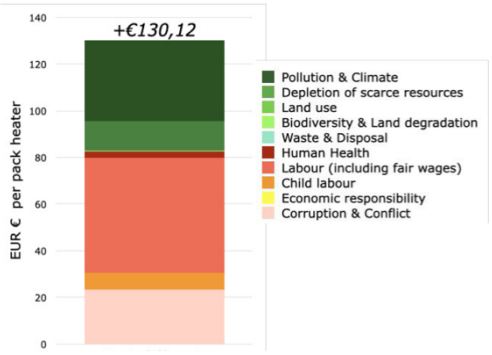

Figure 8. Breakdown negative hidden costs

The main negative hidden costs come from the category Labour. Labour measures fair wages, fair inequality and other labour conditions. The main costs come from the steel workshops as employees receive a

remuneration that is far below the fair minimum wage as determined by the Oiconomy Standard. Employees in the workshops earn € 55- 65 per month, while the fair minimum wage is € 129 per month. Increasing the price of the product so employees receive a fair minimum wage leads to negative costs of € 24,88. Besides fair remuneration, the employees do not receive sufficient contribution to health insurance nor is their occupational health & safety sufficiently managed (€ 3,69). Besides the steel workshops, steel traders were allocated default costs on Labour, as no company-specific data was gathered (€ 9,46). Gathering specific data on the steel trader or cutting out this middle-men could eliminate these costs. The second biggest impact category is Pollution & Climate. The electricity consumed by the steel workshops (€ 12,12), ADMC (€ 9,00), and CO2 emissions during steel production (€ 11,42), contribute mostly to this. The negative costs on Depletion of scarce resources are background costs for the primary production of steel in China (€ 11,42).

Besides negative hidden costs, positive costs were calculated (Figure 9). Bonus ESCU's are based on actual company spending, benefitting others than the ones involved in the transaction. Positive costs of € 17,56 were found, all of this was spent by ADMC. ADMC invested to train their employees, reimburse medical expenses and contribute to a project to prevent child labour, by among other things providing microcredits and by organizing capacity raising activities.

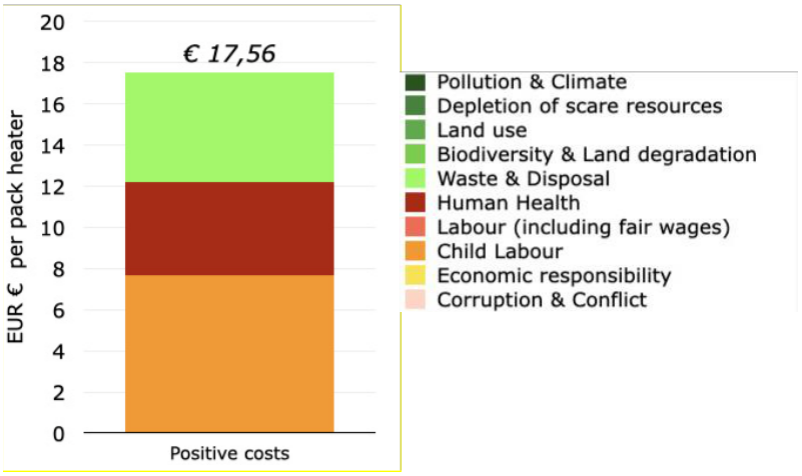

Figure 9 Positive costs per pack heater

3.2.1 Data specificity assessment of pack heater

The data specificity of performance data of this assessment is displayed in Figure 10. ADMC Group was able to complete the assessment using mainly company-specific data. Data on the steel workshops was retrieved through a questionnaire, conducted by a local NGO. Regarding the steel trader and steel producer data was mostly obtained using generic databases.

The data specificity of prevention costs of this analysis are displayed in Figure 11. None of the value-chain partners were able to provide much company- specific prevention costs, as it takes time to make investment proposals to mitigate impact. This should be a focus when the assessment is repeated.

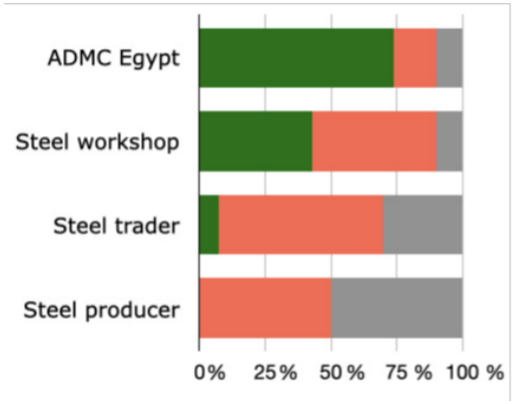

Figure 10 Data specificity of performance costs

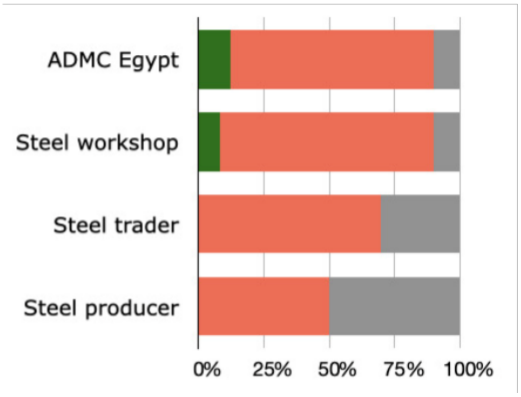

Figure 11 Data specificity of prevention costs

3.3 Case study 3: White pepper

The third company under assessment was Verstegen Spices & Spauces, located in the Netherlands. The product under review was 1 jar of ground white pepper. Verstegen sells white pepper sourced from Indonesia, where the pepper is cultivated by smallholders and sold to the pepper exporter. The supply-chain of white pepper in a jar was traced back by including 80% of the purchased value. This identified the most relevant supply-chains: the plastic cap, the white pepper and the glass jar (Figure 12). The total hidden costs of 1 jar of grinded white pepper are € 1,03 (Figure 13). The sales price of a jar is € 2,99 meaning the hidden costs are adding 34% onto the sales price.

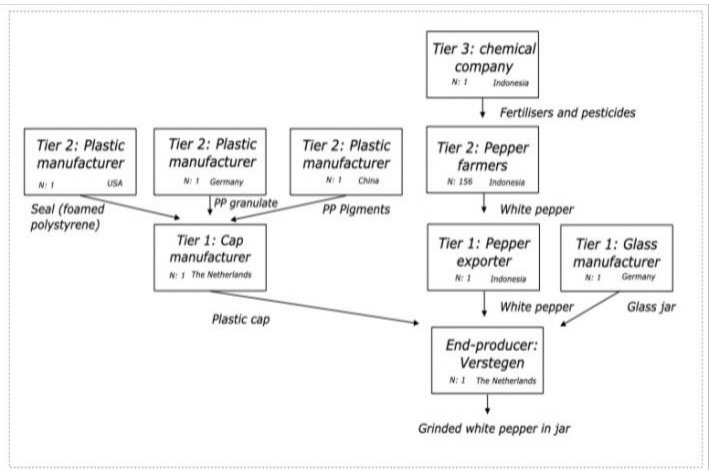

Figure 12 Scope of assessment

Figure 13 Breakdown negative hidden costs

The main negative hidden costs come from the category Labour. Labour measures fair wages, fair inequality and other labour conditions. The glass manufacturer has a salary inequality ratio of 98,7 between the lowest and highest paid salaries within the company. This is above the fair inequality ratio of 23,8. This leads to costs of € 0,76. Additionally, the pepper farmers do not offer their employees health insurance or ensure occupational health & safety (€ 0,04). The second and third biggest cost categories are Pollution & Climate and Corruption & Conflict. Most costs to mitigate pollution are caused by the pepper farmers using fertilizers (€ 0,01) and through the production of glass (€ 0,19). Pepper farmers and pepper exporters are most susceptible to Corruption and have no active governance to mitigate that (€0,04). Other hidden costs that were found, include costs to prevent biodiversity loss. Verstegen, together with the pepper exporter, invested in Agroforestry solutions to increase biodiversity. Through this project, supply- chain specific mitigation costs were used to calculate prevention costs.

Besides negative hidden costs, positive costs were calculated (Figure 14). Positive costs are based on actual company spending, benefitting others than the ones involved in the transaction. Positive costs of € 0,89 were found, 98% of this was spent by Verstegen. Verstegen invested to increase yields, contributing to food security (expressed in the category Land use). The project also led to increased livelihoods of pepper farmers (Economic Responsibility).

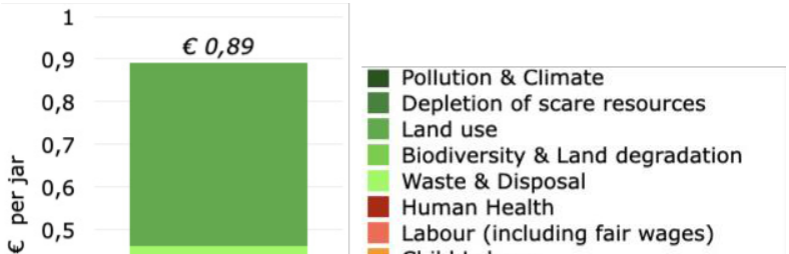

Figure 14 Positive costs per jar of white pepper

3.3.1 Data specificity assessment of white pepper

The data specificity of performance data of this analysis is displayed in Figure 15. Verstegen, the pepper exporter, the pepper farmers and the cap manufacturer were able to complete the assessment using mainly company-specific data. The data of the glass manufacturer was mainly obtained through generic databases.

The data specificity of prevention data are displayed in Figure 16. None of the value-chain partners were able to provide much company- specific prevention costs, as it takes time to make investment proposals to mitigate impact. This should be a focus when the assessment is repeated.

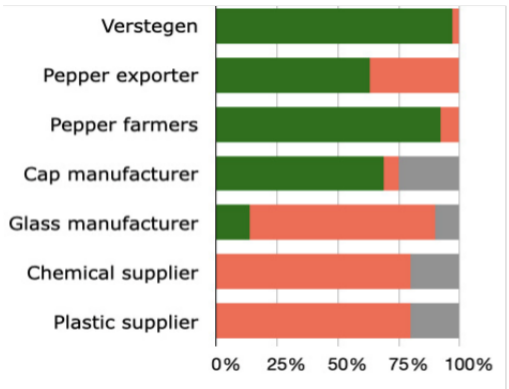

Figure 15. Data specificity of performance costs

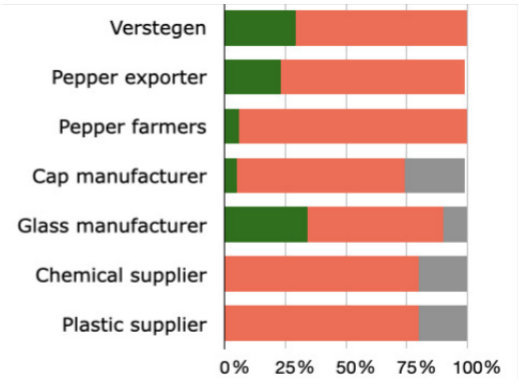

Figure 16. Data specificity of prevention costs

3.4 Main observations and learnings from case studies

The case studies have resulted in observations and learnings that have implications on the Oiconomy assessment tool, further support that is necessary and on further development of the Oiconomy pricing methodology. The following observations were made:

All pilot companies have independently started reaching out to their main suppliers after the initial scoping of the assessment. With the background support from the UU team all three companies were able to complete the full scope assessment.

The pilot companies were in good contact with their main suppliers and were able to convince and motivate the most relevant suppliers to join the pilot. Large suppliers of small elements of the product were hard to convince. In these cases, background-data-based assessments were made. *In the future users will need to be supported in filling such gaps.*

For various aspects, the method includes a self-assessment of the quality of corporate governance, based on the worldwide applied form of management systems, applying the plan-do-check-act approach. The tool includes questionnaires which have been experienced as too detailed especially in the case of small and medium size enterprises. The rationale for using this needs to be better communicated to users, while a simplified version is needed for SME's.

It may be tempting to calculate net positive value by distracting the negative costs from the positives but this is not the intention of the system. The negative hidden costs are derived from prevention of hidden impacts and the positive costs are extra benefits for people and planet. Negative costs cannot compensate the positive costs. In our discussions we see the temptation to do this. *We have to more explicitly communicate the difference.*

Full scope assessment is quite labour intensive the first time, mainly because the companies lack data or the knowledge who has the data even in their own company. Future assessments will therefore be much easier. *Based on the pilot experiences a guidance for starting to use of Oiconomy can be developed. Before starting an assessment, a* ***quick ex ante check*** *on applicability and product scoping can be done. Training opportunities and materials, online available explanations and justifications will be provided in the next stages.*

Where more remote tiers of suppliers (3rd, 4th tier etc.) are involved, it is harder to achieve direct participation and collaboration. This is especially relevant when small or medium size enterprises are involved in middle- or low-income countries. Maintaining the full PPP scope in these cases raises objections of two types: a- the total contribution to the total ESCU of the end-product will be marginal, and b- these remote suppliers may have many other clients, not being interested in such assessments. Despite this **dilution effect** in a specific value chain, the total of small contributions may still be relevant for

prevention. Yet, the fact that the 1st tier suppliers could be involved, also raises the expectation that in the longer term, when the requirement to engage in the system reaches the 3rd, 4th tier etc. suppliers from several customers, these 3rd, 4th tier suppliers can also be engaged. *However, we plan to develop standard ESCU values for a short list of (100-200) inputs in the remote supplier tiers to solve this dilution issue. Most of the environmental default data on remote tier suppliers are already in the system. Science will have to add the socio-economic default data.*

Partly overlapping with this issue is that in remote tiers of suppliers, tool users may need to collaborate with **small suppliers with low level capacities**, not used to business administrations or even illiterate. One can not expect such small suppliers to contribute to the assessment. *We will clarify the role of the supplier tier that is closest to such low developed suppliers, giving them the responsibility of applying the tool.*

The presentation of the overall results shows **very different distributions of hidden costs** between the sustainability aspects. This expressed the tailor-made approach showing the specifics of the supply chains analysed. Some relative high scores as well as very low scores surprised both the companies as well as the UU team. Correctness of the calculations were checked. *In some cases the underlying background data will be re-evaluated. We observe that an interpretation protocol for reading the end results is needed. Relative high prevention costs does by principle not equal relative high priority. Each sustainability aspect identified as have (some) hidden negative costs will need to be addressed. Low costs prevention options may still very well have high impact in reducing emission and unfair social conditions.*

Current positives were sometimes calculated as the positives of the entire organization divided by the % of revenue of the product under review, while they were location specific. However, we aim to only measure the positives linked to specific value chains. *We will adjust the standard by distinguishing rules for value-chain specific positives and organisation-wide positives to the related products.*

The participating end-producers in this pilot found Oiconomy pricing to be a useful tool in starting the dialogue with suppliers, increasing transparency, and jointly working on a more sustainable product. The participation companies also appreciated the insights that an overview of the hidden costs provided as it gives them with a tool to measure the progress towards their sustainability goals. Also, Oiconomy Pricing revealed hidden cost on sustainability aspects that companies were previously unaware of. Overall, the companies found Oiconomy Pricing to be a useful tool in navigating the complex field of sustainability.

4. Conclusion

The goal of the pilot study was to test whether the Oiconomy Pricing tool is clear enough to lead to calculations of hidden cost by company experts instead of external consultants, to identify points of improvement of the

methodology and to test whether the method evokes collaboration about further sustainability performance improvement along the supply-chain.

Applying Oiconomy Pricing, the negative and positive hidden cost of a stone kitchen countertop, a medical device and a jar of white pepper were successfully calculated. The analysis revealed preventative costs of € 32,44 per m^2 stone kitchen countertop, € 130,12 per pack heater and € 1,03 per jar of white pepper. Through the Oiconomy Tool company-experts were guided in making the assessment and sometimes needed additional support from the UU-team. Based on the issues encountered the UU-team was able to improve the Oiconomy Tool and will make training and instructions materials to raise capacity within organizations. Also, several points of methodological improvement were identified: questionnaires to check the quality of corporate governance needed to be simplified for SME's, the relationship between negative and positive costs needs to be clarified and standard ESCU's need to be calculated for raw material producers far upstream in the supply-chain. The pilot reached its objective of increasing supply-chain collaboration to improve sustainability, as the end-producers all started dialogues with suppliers on to lower their environmental and social burden. Additionally, Oiconomy Pricing was able to provide companies with a holistic sustainability assessment of their product, showing preventative costs for sustainability aspects that companies were previously not aware of.

Oiconomy Pricing is relevant as transparency and due diligence are increasingly incorporated into corporate responsibility legislation. Non-financial disclosure is required for large groups of companies, especially in the international market. Full sustainability costs accounting tools can serve the implementation of this new legislation. Also, Oiconomy Pricing can serve as a tool in sustainable public procurement policy, having suppliers substantiate their bids with the Oiconomy price.

Consumers' Attitude for Fish and Seafood in Portugal: Opportunities for footprint reduction and more sustainable consumption

Prof Sara Moreno Pires[1], Dr. Alessandro Galli[2], Adeline Murthy[2], Miss Catarina Madeira[1], Dr. Serena Mancini[2]

[1]University of Aveiro, Aveiro, Portugal. [2]Global Footprint Network, Oakland, USA

Abstract

The habits of seafood consumption have been described as varying substantially from country to country, mainly related to socio-demographic characteristics, regional and traditional factors. Nevertheless, overall, fish consumption and capture in Europe have been increasing over last decade as a result of European fish campaigns and the growth of fish distributors. Portugal has been taking part of this trend, being the third biggest consumer in the world, with 59 kg per capita year. Some explanations for these values include the cultural roots, governmental fish campaigns and the dynamics of the fish market system as well the Portuguese geography, which makes the fisheries and the consumption of fish products extremely value.

Furthermore, food consumption is the single largest driver of Portuguese's Footprint, representing around 30% of the Ecological Footprint of the country. Galli et al. (2020) when analyzing the significance of food in comparison to other daily anthropogenic demands, identified the current sourcing and resource intensities profiles of dietary patterns at Portuguese national and city level through Ecological Footprint Accounting (EFA). Their findings point out that consumption of "fish and seafood" contributes to approximately 26% of the total food Footprint at national level and it significantly depends on production activities outside the national boundaries. Dietary choices in Portugal cause noticeable land appropriation from the biocapacity of ecosystems outside the national borders and "fish and seafood" represents the single highest import of biocapacity from abroad, with about 1.6million gha of biocapacity being imported (about 60% of this food category).

Therefore, with the focus on "fish and seafood" consumption in the country, the aim of this paper is to understand Portuguese Consumers': i) habits of buying and consuming fish and seafood; ii) perception of different fishing methods; iii) attention to environmental issues and sustainability, and iv) barriers to opt for alternative fish and seafood choices. By recognizing what drives seafood consumption choices in Portugal as well as what prevents alternative choices to be made, it is possible to shed light on whether a willingness exist among Portuguese consumers to modify their choices and thus assess the likelihood of transition strategies towards sustainable seafood consumption in Portugal and propose some recommendations and policy orientations.

Consumers' Post-purchase Behaviour of Fashion Products

Arifa Parvin Kemi, Dr. Gyula Zilahy

Budapest University of Technology and Economics, Budapest, Hungary

Abstract

Sustainable consumption is gaining scholarly attention as it has become an essential aspect of designing and implementing national and international policy. The review of the literature regarding fashion consumption shows that most studies focus on consumers' initial purchase willingness and behaviour for fashion products. As a result, to complement previous research, this paper aims to identify and categorize the drivers of consumers' post-purchase willingness and behaviour toward new and second-hand fashion product

The literature on sustainable consumption has grown dramatically, but most have focused on initial purchase decisions. This study went beyond the purchase decision and aims at the post-purchase decision for different types of fashion products. It focuses on consumers' willingness and behaviour to reuse, repair, recycle and repurchase new and second-hand fashion (clothing) products. It compares consumers' post-purchase behaviour of new and second-hand fashion. To complement these research findings, our study attempted to reveal consumers' post-purchase behaviour, asking the following questions: what factors influence post-purchase behaviour towards reuse, repair, and recycling fashion products? What factors influence consumers' post-purchase behaviour towards the repurchase of fashion products? What are the barriers to consumers' post-purchase behaviour towards reuse, repair, recycling, and repurchasing fashion products? We developed our research model with the theory of planned behaviour as a background because consumers' attitudes, subjective norms, and perceived behavioural control considerably impact post-purchase willingness and behaviour of fashion products.

The study's primary purpose was to gain a deeper understanding of how buyers dispose of clothing items and how they respond after purchasing second-hand fashion products. However, it later focused on both new and used textiles to better understand initial purchase behaviour and second-hand product purchase behaviour. The research used both qualitative and quantitative research methods. We have already gone through the qualitative research where second-hand fashion store owners and consumers were interviewed regarding their purchase behaviour patterns.

Based on this, a large-scale questionnaire survey of new and second-hand fashion consumers has been carried out. We surveyed the post-purchase behaviour of 490 individuals through telephone calls. The questionnaire survey used a non-random sampling method to reach a representative group of consumers of Budapest, Hungary. Data will be analyzed using multi-dimensional statistical methods to uncover patterns of post-purchase behaviour. This study states the qualitative research now and later it will analyze the quantitative part in further research. The research results will enable us to understand better the sustainability implications of the new and second-hand fashion market and form suggestions for policymaking relating to this vital sector.

Keywords: Sustainable consumption, fast fashion, second-hand fashion products, post-purchase behaviour, textile fashion products.

Abstract

The food system is a crucial vehicle in sustaining people and their health, supporting their human right to food. Food loss and waste risks this and other rights, in driving negative economic, social, and environmental impacts. Food waste is usually characterized as waste occurring post supply chain, such as at the household, rather than food loss which occurs within the supply chain. Consumers are responsible for the bulk of combined food loss and waste in many global contexts. As such consumer approaches to reducing food waste are imperative.

Date mark labels included on food assist consumers to safely eat it. 'Best before' dates suggest when it may be ideal to consume food prior to, but do not necessarily suggest dates food becomes unsafe. 'Use by' dates advise consumers not to consume labelled foods past a date marked, for safety reasons. Confusion about such date mark labelling is often highlighted as a key driver of food waste in households. Hence calls have been made for clearer date mark labels to reduce food waste.

This paper documents the progress of three related research projects. The projects focus on consumer issues relating to food waste, within the AU$121 million Fight Food Waste Cooperative Research Centre, a partnership linking government, industry, and the academy in Australia to halve food loss and waste by 2030 over a 10-year time frame. Our primary contribution is detailing the role date mark labels play in the industry and consumer contexts analysed by the projects and developing insights into how such labels may be designed more effectively in the future.

We conduct our review by analysing results from the projects thus far. Both small and large companies in industry participated, as did governments, not for profits, and consumers across the socio-economic spread of the Australian population. The research teams carried out surveys, interviews, observations, workshops, and prototype testing were carried out by the research teams. When collated these data paint a distinct picture of date mark labels in relation to consumers, food, refrigerators/ storage infrastructure, packaging, industry product development, and communication. We triangulated data to develop themes that appeared to be either consistent or contrasting across research contexts and stakeholders by taking this approach.

Results show continued confusion over date mark labelling by consumers, and a lack of effective new solutions thus far by industry or government. We identify a need for consistent and clear communications through date mark labelling, and associated education. We conclude by discussing areas for future research for the projects reviewed and new projects. Further work may include; larger research projects aimed at transforming how date mark labels are deployed in the Australian context, likely lead by the Fight Food Waste Cooperative Research Centre; a national consumer behaviour change campaign; and industry/ supply chain integration and assistance in date mark labelling approaches nationally. These options hold promise for better consumer outcomes in food sustainability which is central to United Nations Sustainable Development Goal 12, Target 12.3, to halve food loss and waste by 2030.

Gamified Apps for Sustainable Consumption: A systematic review

Georgina Guillen-Hanson[1], Daniel Fernandez Galeote[1], Nevena Sicevic[1], Dr. Juho Hamari[1], Dr. Jaco Quist[2]

[1]Gamification Group. Tampere University, Tampere, Finland. [2]TU Delft, Delft, Netherlands

Abstract

A considerable amount of research has been conducted on understanding sustainable consumption and different approaches to it. One of them is resource efficiency, which is reflected in SDG 12 with target 8 directly looking into lifestyles. Mobile apps are ubiquitous, affecting our everyday activities and practices because "there is always an app for that." In this vein, there have been a significant number of apps devised to support peoples' lifestyles to make them more sustainable, and this study is set out to draw an overview of the market of gamified mobile apps for sustainable consumption. Following a systematic search, this study analyzes 67 gamified apps regarding their sustainability impact and gamification elements. The findings suggest a tendency to (1) present sustainable consumption as the efficient use of resources to impact the environment positively, rarely addressing societal impacts, potential rebounds, and even economic gains from shifting consumption practices. Other findings include (2) a lack of diversity in gamification strategies, given the prevalence of direct communication with the user, the absence of virtual identities, and most apps targeting behavior change without attitude change. Another potentially problematic design choice is (3) the presence, in some cases, of external rewards that are often contradictory to the message of sustainable consumption as they lead to more consumption. Nonetheless, it is possible to conclude that gamification, the intentional use of game elements in non-game contexts, brings an additional value to motivate shifts in the lifestyles of the apps' users.

Gamification and games play an important cultural and artistic role; they are expressions of specific cultural contexts, while at the same time, they help communicate and even create new forms of culture and art. Our present research aims to develop a blueprint for developers, researchers, and practitioners alike, to encourage them to explore gamification as elements that enable different approaches to consumption, addressing topics such as human rights and rebounds. Besides Target 12.8, our study also touches upon targets 12.2, 12.3, and 12.5, as most apps for SC support individuals and households to manage their domestic material consumption and reduce food waste and waste generation in general.

Other Ways of Living – producing and consuming in pace with nature

Associate Professor Karin Winroth

Södertörn University, Stockholm, Sweden

Abstract

Consumer culture of today often focus on urban lifestyle where technique, success and social media play crucial roles. The medialized culture offers an arranged version of reality in which filtered photos and visible signs of success and happiness are in focus. Already have researchers and doctors underlined how this media version of lifestyles create anxiety and neuroses.

There are, however, other ways of living. By highlighting and illustrating lifestyles and consumption in line with sustainable ideas, other models for how to live and other ideals become more publicly available. This paper introduces two examples of producers, one offering services and one offering products, where the production as well as the consumption is in line with sustainable living. The aim of the paper is to answer the question: what makes these two cases illustration of sustainable production processes as well as sustainable consumer processes? In addition, what can other firms learn from this?

The methods used for the empirical data is a combination of text analyses, interviews, observation and actual consumption of the product and service. The findings illustrate how consumption of these product/service is both comfortable but also educational. They offer insights into lifestyles in harmony with nature as well as knowledge of how to preserve natural resources. The conclusion of the paper is how important it is for people to be introduced to sustainable lifestyles and to experience and learn about nature to develop a respect for its' resources.

This abstract especially relate to 'STG+target: 12, more specifically 12.2, 12.8, 12c'.

Proposed contribution relates to the topic of the Conference SUSTAINABLE DEVELOPMENT AND COURAGE: CULTURE, ART AND HUMAN RIGHTS by highlighting how lifestyles are embedded in culture. In addition, it can be cultural traditions and knowledge passed over generations that become crucial knots for producing according to sustainable ideals.

Prosumption - state of the art and implications for sustainable development

Dr. Ádám Csuvár, Dr. Gyula Zilahy

Budapest University of Technology and Economics, Budapest, Hungary

Abstract

Exploring the perspectives for a sustainable society in the 21st century, Alvin Toffler argues in his book, 'The Third Wave' (Toffler, 1980) that the number of classic consumers of industrially provided goods will decline and will be replaced by 'prosumers': people producing and consuming goods and services for their own and other's consumption (Ritzer and Jurgenson, 2010).

Since then, a number of definitions of prosumption surfaced and the fast growing number of prosumers and the increasing importance of prosumption in the economy slowly started to spur scientific inquiry into the topic. In 2009 Ritzer discussed the 'age of prosumer' (Ritzer, 2009) just to be followed by others characterising prosumers and certain types of prosumption activities (see e.g. Blättel-Mink and Hellman, 2010; Collins, 2010; Comor, 2011; Humphreys & Grayson, 2008; Ritzer, 2010; Ritzer & Jurgenson, 2010).

Prosumption promises solutions to many of today's problems. Consumers may gain from producing goods and services in several ways including, but not limited to financial savings, self-employment, improved social relationships, the satisfaction arising from engagement in creative activities, etc. Similarly, corporations may gain direct and indirect financial benefits from utilizing resources provided by prosumers for free or for a fee.

For society, prosumption may bring the benefit of the empowerment of people (by education and learning) and democratization; a more efficient use of resources; the implementation of the ideas of the circular economy; economic benefits to marginalized regions; raised resilience, etc.

However, it is not self-evident that actors make use of these benefits and the sustainability potentials of the prosumption economy can be utilised. For instance, services provided through sharing economy platforms may not be based on the best available technologies (e.g. using outdated cars, apartments with inefficient heating, etc.) and prosumers installing solar panels may increase their electricity consumption as a result of lower energy costs (Ottelin et al., 2017).

To this end, an ongoing research project at the Budapest University of Technology and Economics aims at a better understanding of prosumption activities and their environmental and social implications.

During the first stage of the research, business models facilitating prosumption, as well the potential environmental and social impacts of increasing prosumer activities have been identified and characterized based on desk research. The results of these investigations will be demonstrated along with the results of an ongoing qualitative empirical research implemented in Hungary, which targets the identification and characterization of actual presumption activities including the types of activities, their frequency and distribution in space and time and the motivation factors of and barriers to different prosumption activities.

Sustainability-Related Consumer Attitudes Towards Ecological Food Products: Does a consumer healthy lifestyle determine them?

Prof. dr. Jurate Banyte, Assoc. prof. dr. Agne Gadeikiene, Assoc. prof. dr. Aiste Dovaliene, Prof. dr. Zaneta Piligrimiene

Kaunas University of Technology, Kaunas, Lithuania

Abstract

The discourse on sustainability is widely evident in studies on food product consumer behavior, e.g., sustainable food choice motives (Verain et al., 2015) or sustainable consumption dimensions (Fischer et al., 2017) are being analyzed. Verain et al. (2021), in their developed Sustainable Food Choice Questionnaire (SUS-FCQ), looked to sustainability through the assurance of animal welfare, reduction of environmental harm, fair trade, local product choice. Such characteristics as food taste, price, or purchasing convenience are also considered relevant from the sustainable consumption perspective. In the Thøgersen (2017) study, food taste and price were analyzed as the factors influencing sustainable food consumption. We agree with this opinion and argue that the holistic evaluation of sustainability-related consumer attitudes requires to include attributes of so-called utilitarian consumer motives ("tasteful", "expensive", "cheap", and "easily accessible"). Other selected attributes correspond to the categories of SUS-FCQ (Verain et al., 2021): animal welfare ("vegan", "animal-friendly"), environment ("environment-friendly", "produced while responsibly using resources"), fair trade ("fair trade"), local product choice ("locally produced"). The attribute of ecological food product "healthy" is related to Sautron et al. (2015) suggested category "health and well-being", and attributes "high quality", "natural", and "organic" – to the category "miscellaneous".

This study considers consumer healthy lifestyle as determining sustainability-related attitudes towards ecological food products, food consumption habits, and general health-related beliefs. We adopt four consumer healthy lifestyles described by Gadeikiene et al. (2021).

According to the above-mentioned arguments, this study aims to investigate different healthy lifestyle consumer segments' sustainability-related attitudes towards ecological food product attributes. In this study, we employed indirect measures of implicit attitudes in addition to explicit attitude measurement. We asked respondents to express their attitudes to the attributes characterizing ecological food products (explicit test) and also measured the reaction time (implicit test). A total number of 302 respondents representing different healthy lifestyles participated in the study.

The research results demonstrate that the majority of the respondents consider ecological food products as "expensive", "natural", "healthy", "environment-friendly", "high quality". They disagree that ecological food products are "cheap", "vegan", "easily accessible", "locally produced", and "fair trade". Measurement of the implicit attitudes shows that the certainty of the respondents in their attitudes is medium. The results contradict our initial assumption that consumers' attitudes towards ecological products might be determined by a healthy lifestyle. Respondents representing segments "unhealthy lifestyle representatives" and "mental well-being oriented" agree with fewer attributes characterizing ecological food products than those of the other two segments. Evaluation of the implicit attitudes showed that respondents from the segment "healthy lifestyle guru" very quickly react to the attribute "cheap". However, this attribute is not selected among the majority of the respondents.

References available upon request.

SDG+target: 12.3, 12.5, and 12.8.

The proposed contribution relates to the topic of the Conference as it offers a holistic understanding of sustainability-related consumer attitudes towards ecological food products. It could be beneficial for public and private bodies that appeal to consumers of different healthy lifestyles and seek to encourage a more thorough general understanding of sustainability issues in the food sector.

Analysis of Wastage Mechanisms in the Supply Chain of Fish Products in a Circular Economy Perspective: An empirical research

Survey to Italian families on the food waste of fish products.

Abstract

The fish waste problem at the consumption phase and the rational management of fish products is one of the central matters of the transition process undertaken by the European Union, especially within the new Action Plan for Circular Economy and it is widely debated in the literature. Due to the exploitation of the entire chain of fisheries and Fishery products, significant damage is caused to the marine ecosystem, which is already, heavily, damaged by anthropocentric actions. Report of the field is agreed that fish products are going to be insufficient to cover the trending demand for consumption. The number of species at risk of extinction is constantly increasing the need to protect marine ecosystems has become a global priority. The waste of these products occurs throughout the supply chain. Specifically, the consumption phase generates a strong economic, social and environmental impact. Literature and studies analyzing food waste on this subject, mainly focus on the first part of the fishing supply chain fisheries, This work aims to investigate the mechanisms and causes of wastage that occurs in the last part of the supply chain. Specifically, this link in the chain presupposes an interaction between the distributor and the consumer conditioned by factors such as quantity (availability of the product), quality, behavior and consumption habits of the final customer. This last aspect has been drastically modified in the light of the Covid-19. The work focuses on the analysis of food waste at the final stage of fish consumption, generated by Italian families and the change in consumption habits, as a result of the restrictions brought by the pandemic. To investigate what actions, habits and behaviors contribute to waste, a survey was conducted. The causes of waste have been identified by framing them in the two dimensions of final consumption, such as consumption in the home and consumption outside the home. The research has the ambition to enrich the existing literature to clarify the determinants of waste in the final consumption phase. A special feature of the research is the current pandemic situation. The scenario of the complete closure of the catering activities has been projected, examining whether the consumption change of households in taking advantage of the takeaway, modified the volume of waste produced in the home. Two

logit models have been used to identify whether factors identified as causes may increase or decrease the waste product. The construction of the survey system is consistent with the methodologies used in the literature for the study of food waste. The results of the models have found several factors influencing the generation of food waste of fish products six inside that out of the house, to each of these variables have been proposed different strategies. The proposed basic strategies focus on awareness-raising, and culinary education, through the implementation, planning and promotion of information channels. The research topic falls within the Sustainable Development Goal 12 for responsible consumption. Specifically, the 12.3 target and at 12.3.1b sub-indicator.

Keywords: Food waste fish, Consumer behaviour, Logistic regression, Prevention and culinary education

1. Introduction

Fishery products are an important food source providing approximately 17% of animal protein consumed globally. Their consumption has reached 20.5 kilograms per capita per year and will tend to increase in the coming decades [1]. Notwithstanding the current Covid-19 pandemic crisis, the European consumption of Fishery products has shown no signs of receding [2]. Fishery products are perishable foods that have a high potential for waste and loss. The waste of fishery products is a problem of particular concern due to growing global demand, unsustainable fishing and aquaculture practices and the high propensity to waste. The loss and waste of fishery products occurs throughout the supply chain [3], bringing further impacts to the resource already heavily damaged by marine degradation, all geographical areas are involved in generating waste both in the primary production phase and in the final consumption phase [4]. It has been observed that developing countries tend to generate food loss, i.e. aimed at the early stages of the supply chain, usually attributed to inadequate handling, processing, and commercialization practices [5]. In the high-income countries, in contrast, food waste is more consistent with the retail, restaurant and household level [6]. A recent evaluation [7]estimated that 35% of the global fish crop is wasted every year. Reducing losses and waste of fish products can lead to a reduction in pressure on fish stocks and help improve resource sustainability as well as food security. Food waste, identified as " *food appropriate for human consumption that is discarded or left to deteriorate at the consumer level regardless of the cause"* [8], has become an increasingly relevant topic in recent years due to the economic and environmental burden it entails. It is estimated that each year about 1/3 of the food produced becomes waste, which is equivalent to about 1.3 billion tons of wasted food [9]. The pressures of food waste have influenced the United Nations (ONU) in setting the goal of halving world food waste and substantially reducing global food loss by 2030 (SDGs 12, target 12.3) as part of its program of 2030 Agenda [10]. FAO and UNEP are the managers of indicator 12.3 and retain they can subdivide the indicator into two sub-indicators as there are different drivers along the food chain that generate different food waste or losses. Sub-indicator 12.3.1b monitors and measures waste in the last stages of the supply chain, the

measurement methods can be different, questionnaires, interviews, surveys, statistical coefficients and agendas are the most widespread in the scientific field [11]. According to the latest revision, the sub-indicator is classified at tier2 [12]. About 931 million tons of food waste were generated in 2019 [11], 61% of which came from households, 26% from catering and 13% from retail. Similarly, the EU produces 88 million tonnes of food waste and only households generate more than half, 47 million tonnes, followed by restaurant services and retail trade [13]. Through the communication on the circular economy, the EU[1] will set new objectives to reduce food waste as a key action within the "Farm to Fork" strategy (*Farm to Fork Strategy For a Fair, Healthy and environmentally-Friendly System*, n.d.). Quantifying food waste is essential for the development of effective prevention and reduction strategies and for verifying their effectiveness over time [15]. To reduce fish waste, it is necessary to understand how to quantify the waste and how it occurs. To date, few studies have been published relating to the quantification of fish food waste at European and international level. These studies focus on catches [16], production [5], industrial processing [17] and catering activities (on the restaurant side) [18] while the information on fish waste in distribution and households is currently poor, scarcely exportable and focused on food waste in general instead than on a single food [19]. This study focused on the generation of food waste of fish products by Italian families and on investigations of the reasons behind the waste both inside and outside the habitation. The survey is presented as first research aimed at quantifying fish waste in high-income families, differentiating the waste produced inside and outside the home. A relevant peculiarity of the research lies in the consideration of the current pandemic crisis. Analyzes were carried out on the general causes of waste outside the home, before the various closures of the catering activities for the containment of the virus. The scenario of the current pandemic crisis was observed, examining whether the change in consumption of families in taking advantage of home delivery of fish-based dishes, has changed the volume of waste at home. The research questions to be answered are the following: *i) What are the causes that determine the food waste of fish products in the home? ii) What are the causes that determine the waste of fish products outside the home? iii) Did home delivery during Covid-19 containment change the waste of fishery products produced indoors?*

2. Methods

A questionnaire was developed to answer the research questions. For the realization of the questionnaire, an analysis of the literature existing in the various bibliographic databases was carried out, in particular ScienceDirect. The various studies dealing with food waste and methods of quantifying domestic food waste were filtered out. The questionnaire method is widespread in the literature [20][21][22][23][24][25][26].

[1] COMMUNICATION FROM THE COMMISSION TO THE EUROPEAN PARLIAMENT, THE COUNCIL, THE EUROPEAN ECONOMIC AND SOCIAL COMMITTEE AND THE COMMITTEE OF THE REGIONS A new Circular Economy Action Plan For a cleaner and more competitive Europe COM / 2020/98 final

The study was conducted from May 2021 to July 2021. A questionnaire was created through the Google Form platform. The questionnaire was disseminated on various social platforms (e.g., Facebook and Instagram). Participation was voluntary and anonymous. The questionnaire consists of 24 open and multiple-choice questions, divided into four areas. The first section investigates domestic consumption, purchasing preferences, the place of purchase, trends and fish products purchasing habits. The second section focuses on the frequency of out-of-home meals based on fish products before the restrictions for contagion from Covid-19 and the frequency of take-away foods containing fish products, during the closing period of the catering activities. The third section concerns questions on the knowledge of food waste and the self-quantification of the waste of fish products both inside and outside the habitation, associating the causes for which the waste occurred. The fourth section is regarding socio-demographic questions. The definition taken into consideration for the research is the one proposed by [8]. To identify the factors and causes that generate fish waste, two logistic regression models were used through the Gretel software. The Logit model is mainly used in the social sciences [27], it serves to describe the probability of a relationship between a dichotomous variable and one or more quantitative or qualitative variables. The Logit model is a widely used methodology in the literature for estimating the probability of increasing or reducing food waste according to various factors [28][29][30][31][32]. For the quantification of fish waste produced inside and outside the home, it was asked to self-declare the waste threshold in a numerical range from 0 to 100. The technique used for the quantification has already been tested in other studies dealing with food waste in the last stages of the supply chain. For the self-reported quantification of waste both inside and outside the home, two logistic regression models were estimated. The dichotomous dependent variable of indoor fish waste is defined through the indications of [33], suggesting the value in which fish waste occurs is estimated through the arithmetic mean of the self-declared value of the sample, in the research the observed threshold value for waste is equal to $\chi = 14.5$. The dichotomous dependent variable of food waste was estimated according to the study [34], suggests considering identifying waste in restaurants with a self-reported value greater than or equal to five. The independent variables used for the logistic regression model for waste inside and outside the home and their modalities are shown in Table 1.

Table 1 *Description of the variables*

Dependent variable: waste of fish products Inside the home		**Dependent variable: waste of fish products Outside the home**	
Variable denomination	*Definition*	*Variable denomination*	*Definition*
Low frequency of consumption	Less than once a week	Low frequency to the restaurant	Less than once a month / once or twice a month
Medium frequency of consumption	Once a week	Medium frequency to the restaurant	Less than once a week / once a week
High frequency of consumption	Two or three times a week / Four or more times a week	High frequency to the restaurant	Two or three times a week / four or more times a week
Purchasing Responsibility (Me)	Me / Me, along with another member of my family	Food Waste Knowledge	Values range from 0 to 5
Medium frequency of takeaway	Less than once a week / once a week	Satiety	Values range from 0 to 5
High frequency of takeaway	Two or three times a week / four or more times a week	Different expectations	Values range from 0 to 5
Never use take away	Never used the take away	Wrong meal	Values range from 0 to 5
Food Waste Knowledge	Values range from 0 to 5	Fish cleaning	Values range from 0 to 5
Excessive purchases	Values range from 0 to 5	Doggy-bag	Values range from 0 to 5
Excessive culinary preparations	Values range from 0 to 5		
Malodor	Values range from 0 to 5		
Product expiration	Values range from 0 to 5		
Visceral parts	Values range from 0 to 5		
Different taste	Values range from 0 to 5		
Incorrect preservation	Values range from 0 to 5		
Reuse waste	Values range from 0 to 5		

The extrapolation of the independent variables to choose to build the probabilistic regression models focused on existing research in the quantification of food waste and consumer behavior both inside and outside the home, the most appropriate ways to investigate the research were chosen. It is suggested to search in the independent variables inside the home, the frequency of consumption [35], the person responsible for the purchases and the knowledge of the impacts on food waste [36]. For the causes that identify the waste produced indoor, the most frequent and consolidated causes taken from previous studies have been attributed [37], [38], while reuse has been identified as a method to reduce waste [39]. The take-away consumption frequency has been inserted to seek the change in consumer behavior due to the closure of the restaurant

activities, which has led to a change in generating waste. It is suggested to search in the dependent variables outside the home, the frequency of consumption at the restaurant [40], the knowledge of the impacts of waste. The possible causes to which waste can be generated outside the home [34], the doggy bag is identified as a tool to reduce waste [41].

3. Results and Discussion

An amount of 161 Italian families residing in Lazio (Viterbo and Civitavecchia) participated in the questionnaire. The socio-demographic characteristics of the sample are reported in table 2.

Table 2 *Characteristics of the sample*

FEATURES	DISTRIBUTION OF THE SAMPLE
Gender	102 - Women (63.35%) 59 - Men (36.65%)
Average age (range)	41.62 (from 18 to 85 years old)
Residence area	35 - Coastal area (21.74%) 126 - Inland area (78.26%)
Nuclear family	33 - Presence of children up to 12 years (20.50%) 128 - No children (70.50%)
Education level	6 - Primary education (3.73%) 72 - Secondary education (44.72%) 83 - Higher education (51.55%)
Monthly wage	53 - first income bracket 0 € - 1000 € (32.92%) 91 - second income bracket € 1001 - € 2500 (56.53%) 17 - Third income bracket > € 2501 (10.55%)

The descriptive statistic of the dependentvariable FWHOUSEHOLD is reported in Table 3

Table 3 *Descriptive statistics FWHOUSEHOLD*

"FW HOUSEHOLD"	
Average	14.460
Median	10,000
Mean square deviation	16.081
Min	0.00
Max	70.00
Coefficient of variation	1.1122

As the first aspect, the sample mean is equal to (14.46), the median value is equal to (10), the mean square deviation (16.081), the Min value assigned for waste is equal to zero and the Max assigned to waste is equal to (70). The technique used for the dichotomization of the FWHOUSEHOLD variable revealed that in the sample (59) respondents declared a value above the average, while the rest (102) assigned a value below the average.

The descriptive statistics of the dependent variable FWOUTHOUSE are shown in Table 4.

Table 4 *Descriptive statistic FWOUTHOUSE*

"FW OUTHOUSE"	
Average	16.950
Median	10,000
Mean square deviation	19.161
Min	0.00
Max	70.00
Coefficient of variation	1.1304

It is noted that the self-declared mean of waste of the sample is equal (16.95), the median value is equal to (10), the standard deviation is equal to (19.161), the Min value assigned for waste is equal to zero and the Max declared waste is equal to (70). The dichotomization technique of the variable revealed that (111) families declared a waste greater than 5% when eating fish outside the home, the remaining (50) declared a lower value.

The results of the logistic regression model of the factors affecting the significance of the dichotomous variable FWHOUSEHOLD are shown in Table 5.

McFadden 's R-framework				0.358169	
Number of cases 'predicted correctly'				132 (82.0%)	

As the first aspect of the model we note its goodness of fit, the value of Mcfadden 's R-square is equal to 0.358169. The value is in line with scientific studies on food waste through a self-declaration methodology of waste with qualitative variables [34][20]. The results are described below:

Wage: the *average wage* variable was considered as the base variable in the model. The model returns the coefficient of the *average wage* variable with a positive value, at a significance level of $\alpha = 0.05$. The result is interpreted as an increase in income, probably corresponding to a greater food waste of fish products inside the house. This result confirms studies by [42][43], agree that people with higher wages waste more than people with lower wages.

Age: The model returns the coefficient of the variable *age* with a negative value, at a significance level of $\alpha = 0.01$, the result from the model is interpreted, as young people probably waste more fish products indoors than adults. That finding is in line with the studies of [44], [45], [46], which agree that young people waste more than adults.

Consumption: In the model, the *high frequency of consumption* category was considered as the basis. The model returns the coefficient of the *average frequency of consumption* variable with a positive value, at a significance level of $\alpha = 0.01$, this response is interpreted as the probability of an increase in consumption can generate an increase in waste. The hypothesis of generating more waste as the frequency of consumption increases may depend on several factors, such as behavioral norms, social norms and procurement practices. The higher availability of consumption leads to an increase in waste compared to those who consume a minimum quantity, the result of the model on the trend of the frequency of consumption reflects the studies of [47][48] agree that an increase in the frequency of consumption can increase the threshold for food waste in the home.

Purchasing responsibility: The value of the coefficient of the *Purch.Respons.ME* variable is positive at a significance level of α: 0.05. This response is undertaken as communication and the involvement of the purchase within the family unit can decrease the food waste of fish products inside the home. This result is confirmed by the studies [49] stating that the involvement and participation in the purchase phase helps to decrease the food waste produced at home.

Home deliveries: During the current pandemic crisis, the service of home deliveries by catering businesses has been encouraged. We want to investigate whether the frequencies of home deliveries have contributed to increasing the food waste of fish products inside the home. The variables inserted in the model are *low frequency of takeaway*; *medium frequency of takeaway*; *high frequency of takeaway*; *never takeaway*. The *never takeaway* variable was omitted from the model in the response phase of the results. The model returns the coefficient of the *medium frequency of takeaway* variable with a positive value, at a significance level of α: 0.05. The results show that increasing the frequency of home delivery can probably generate an increase in food waste produced.

Knowledge and awareness: The response of the model on knowledge and awareness of food waste, it is possible to assume that food waste is probably higher in people who believe that food waste is not

interconnected with human health and the environment. The model returns the coefficient of the *Food Waste knowledge* variable with a negative value, at a significance level of α = 0.05. The knowledge of food waste and the involvement of food waste understood as the level of awareness and concern of the problems related to the phenomenon, have a proven effect on waste behaviors, in [50] it's believed that people who are aware of the problem of food waste are more likely to avoid of wasting food.

Excessive purchases: the excessive purchase is one of the main causes of food waste in the home [51]. The model returns the coefficient of the variable *excessive purchases* with a positive value, at a significance level of α = 0.05, this result is interpreted as the increase in the purchase quantities of fish products corresponds to an increase in the probability of increasing the waste. The model's response agrees with studies by [52][53]. buying more food than necessary increases the likelihood of spoilage.

Malodor: The coefficient of the *malodor* variable is positive with a significance level of α: 0.10. This result is undertaken as with the increase of the bad smell of a fish product, its possibility of becoming waste increases. The product must have good sensory capabilities because they help us determine the freshness of food in order to minimize or prevent waste [54].

Different taste: The coefficient of the *different taste* variable has a positive value with a significant level of α: 0.05, this result shows that variations in taste compared to expectations increase the probability of generating waste.

Incorrect preservation: Incorrect preservation has been included as a cause variable for the food waste of fish products. The model showed that the likelihood of improper conservation for fish products does not affect waste. The interpretation of the result shows that the sample has a good knowledge of the method of conservation of the various fish products.

Reuse: The coefficient of the *reuse* variable takes on a negative value at a significance level α = 0.10. The model shows that people who do not reuse fish product waste are more likely to waste. [33] showed that individuals who do not recycle or compost any of their kitchen waste tend to throw away more food than those who reuse kitchen waste.

The results of the probabilistic regression model of the factors that influence the significance of the dichotomous variable food waste of Fishery products outside the home are shown in Table 6.

Wrong meal	−0.521014	0.238497	−2.185	0.0289	**
Fish cleaning	0.490758	0.213059	2.303	0.0213	**
Covered	0.332175	0.242696	1,369	0.1711	
Doggybag	−0.291299	0.149629	−1.947	0.0516	*
McFadden 's R-framework				0.200312	
Number of cases 'predicted correctly'				132 (82.0%)	

As the first aspect of the model we note its goodness of fit, the value of McFadden 's R-square is 0.200312, The value of the goodness of fit is comparable to studies of [33], [55]. The results are described below:

Satiety: In [56] it's believed that satiety due to portion sizes is a major cause of food waste in the catering industry. In line with this study, the model demonstrates that the coefficient of the satiety variable is positive with a significance level of α: 0.01, proving that the higher an individual's level of satiety increases, the greater his relative waste.

Wrong meal: The model returns the variable with a negative coefficient value at a significance level of α: 0.05. Therefore, this result is interpreted that despite errors in the communication or assembly phase of the order, the probability of food waste from fish products outside the home does not increase.

Fish cleaning: Respondents were asked to self declare whether cleaning the fish product (for example breaking the shell, removing the bones, etc.) could contribute to increasing the level of food waste from fish products outside the home. The model demonstrates that the coefficient of the *fish cleaning* variable is positive at a significance level of α: 0.05. We can therefore hypothesize the probability of increased food waste of fish products when the courses are served with the presence of shells, bones or carapaces.

Doggy-bag: Using the doggy bag is a good way to reduce food waste in the catering sector.
The coefficient of the doggy-bag variable is negative at a significant level of α: 0.1. In line with the study by [28] shows that not requiring the doggy bag for the leftovers has a greater chance of generating waste.

The research has some limitations. Since there is no univocal definition of food waste, many hypotheses are created to define the food waste of fish products, both for the variety of products, for the organoleptic differences, and for the various variables of deterioration of the fish product. The elaboration of the questionnaire was carried out through the analysis of single scientific studies dealing with food waste for a wide range of products. Furthermore, the [11] in the guidelines for the quantification of food waste, does not recommend using the questionnaire as a quantification methodology. It proposes to use the questionnaire as a method to deepen and enrich the research with additional information. The methodology proposed for the research is also limited in the European field, the decision of the European Commission[2] proposes to combine the questionnaire with a methodology aimed at increasing reliability and relevance. In contrast to the limits of the research, the study [57] believes that questionnaires are structured and formal ways to collect quantitative and qualitative data among all the actors of the agri-food chain, from producers to consumers, they are convenient, usually standardized, accessible and easy to read.

4. Conclusions

The investigation is a first step in the search for fish waste in the final consumption phase, the research lays the foundations in deeper exploration in the phenomenon in question. An interesting data emerged during the analysis of the results of the food waste of fish products inside the house turns out to be the takeaway frequencies during the periods of closure of catering activities. From the analysis of the significance of the frequencies of the takeaway it turns out that to an increase of the fish waste produced inside house can make

[2]Commission Delegated Decision (EU) 2019/1597 of 3 May 2019 supplementing Directive 2008/98 / EC of the European Parliament and of the Council as regards a common methodology and minimum quality requirements for the uniform measurement of levels of food waste (Text with EEA relevance.)

to verify an increase of the produced waste inside house. This result is destabilizing, as the change in consumption due to the incidence of the takeaway phenomenon can lead to an increase in fish waste produced indoors. Various solutions are expressed to mitigate this expectation: the restaurateur offers the consumer the possibility to choose the quantity of fish-based dishes in the home delivery phase. This solution has two enormous advantages, the economic and environmental savings for the consumer. Ordering less quantity of food leads to a reduction in expenditure and therefore generates economic savings for families, while reducing the quantity of portions ordered contributes to the reduction of waste. Another possible alternative is the commitment by the restaurant activities to encourage the use of leftovers, recommending possible solutions for subsequent preparation. This type of information would be fundamental for the reduction of fish food waste due to home deliveries and at the same time increase the knowledge of the techniques for reusing fish leftovers, another factor that greatly affects fish food waste. The model of food waste of fish products in the home returns two significant variables, which deserve particular attention, the different taste compared to expectations and the practice of reusing food waste from fish products. The interpretation of the different taste variable of the food waste model of fish products at home, believes that there is the probability of an increase in waste of the fish product, when the product has a different taste than imagined expectations. This divergence can be addressed by increasing information on the organoleptic properties of the various fish products and promoting culinary education campaigns for the various fish products. Contributing to the dissemination of prevention and culinary education is already a recognized solution to reduce the production of food [58] waste. A fundamental aspect for possible future developments is to direct these policies towards young people, given their greater incidence in generating fish waste inside home. Another aspect that emerged that contributes significantly to generating food waste from fish products at home is the technique of reusing leftovers / waste from fish products for subsequent preparations. From the replies to the questionnaire it emerges that the reuse technique is not much appreciated by the sample and this situation is projected into an increase in fish waste produced at home.

The solution devised to increase the technique of reuse of leftovers / scraps of fish products, focused on the will and intent of the consumer to reduce their waste, the reuse technique could be increased, using communication channels to show with evidence practices, new culinary recipes that include the reuse of fish product waste, praising its advantages, including economic savings. Satiety of the courses and the use of the doggy-bag are the significant variables worthy of a discussion of the food waste of fish products outside the home. During the administration of the questionnaire, it was asked whether the dishes ordered lead to a sense of satiety on the part of the interviewees before they are able to finish the dishes. The response of the model to this variable was to believe that the sense of satiety affects the variable waste outside the home, determining

the probability of generating waste as the sense of satiety increases due to the portions of fish-based dishes. A plausible solution, to be implemented in food waste prevention strategies within the restaurant business, is the one proposed by [59] suggesting a model that can be adopted by both the restaurateur and the customer, i.e., inserting the quantity of portions in the menu suggesting whole portions or half portions, in order to limit the amount of waste, of course the cost of half portions will be cheaper than whole portions. This hypothesis leads to two very important advantages, limiting waste and saving money. To stimulate the use of the diversification of the portion quantities in the menus by restaurateurs, it is believed that the public body must encourage and support the activities that adopt prevention strategies against food waste, through the disbursement of subsidies or incentives, so that the use of half portions becomes a common norm. A relevant factor that contributes significantly to the food waste of fish products outside the home is the doggy-bag. The result of the logistic model demonstrates that not using the doggy-bag can probably lead to an increase in fish waste produced outside the home. Encouraging the use of the doggy-bag can therefore lead to the generation of less waste. Studies [60] show that encouraging consumers to adopt doggy-bags requires increasing the perceived benefits of using them and reducing negative emotions such as shame. To implement the doggy-bag strategy, it is necessary that the public body be the guarantor of the education and prevention campaigns of food waste, encouraging its use and increasing its practicality, reversing negative thoughts into proactive ones and encouraging catering activities. who practice the spread of use. The results show that it is essential to create information channels to enrich skills in preventing waste, it is important to involve young people in these initiatives, as they are the most responsible. From the analysis it emerged that some factors influence the probability of food waste of fish products inside the home, including buying in excessive quantities, which can be attributed to incorrect planning in the purchase phase or to incorrect communication within of the family unit. Paying more attention in the purchase planning phase or checking inventory can reduce the excess of fish products purchased and consequently reduce their waste. The bad smell increases the probability of waste, this situation can arise from various aspects, incorrect preservation, expiration date exceeded, or the purchase of the product already damaged. To reduce the bad odor factor, it is advisable to check the product label, make sure it came from and when it was caught. Incorrect preservation of the fish product does not appear to be influential in the model and a good education in the methods of conservation of fish products by the sample is assumed. From a circular economy perspective, the reuse of fish products is the most useful practice in limiting the food waste of fish products, contributing to enormous benefits ranging from economic savings, mitigating the enormous pressures on fish resources, reducing the environmental impact and the possibility of creating a second raw materials market based on the waste of fish resources, which today, thanks to new technologies and various experiments, it is possible to reuse the waste of fish products in a second life. A discordant factor of the waste of fish products both inside and outside the home is the presence of visceral

parts, they do not appear to be significant in the waste inside the home, but they appear to be a cause of waste outside the home, indicating that the cleanliness of the product is perceived in a way different from the sample according to the place where it is consuming fish products. Encouraging the request for the doggy-bag is a possible solution to limit the waste generated outside the home. The sample does not show a positive attitude to the use of the doggy-bag, in fact, more than half of the sample has never taken this action. It is therefore important to make people aware of this topic. The results of the study may support future research aimed at developing strategies to mitigate fish waste generated during the consumption phase. Although the focus of this research is focused on a specific point in the fisheries supply chain, the findings may have broader implications for reducing waste at a wider level. The research provides a better understanding of what drives the generation of fish waste by Italian families both inside and outside the home, the research paves the way for new studies that focus on the waste of a certain food. The search may also be applicable to other regions.

Emerging Prosumers and Company Management – A stakeholder approach

Adam Csuvar[1], Gyula Zilahy[2]

Abstract

Prosumption promises solutions to many of today's problems. Consumers may gain from producing goods and services in several ways including, but not limited to financial savings, self-employment, improved social relationships, the satisfaction arising from engagement in creative activities, etc. Similarly, corporations may gain direct and indirect financial benefits from utilising resources provided by prosumers for free or for a fee. For society, prosumption may bring the benefit of the empowerment of people (by education and learning) and democratization; a more efficient use of resources; the implementation of the ideas of the circular economy; economic benefits to marginalized regions; raised resilience, etc. However, it is not self-evident that actors make use of these benefits and the sustainability potentials of the prosumption economy can be utilised. For instance, services provided through sharing economy platforms may not be based on the best available technologies (e.g., using outdated cars, apartments with inefficient heating, etc.) and prosumers installing solar panels may increase their electricity consumption because of lower energy costs). To this end, an ongoing research project at the Budapest University of Technology and Economics aims at a better understanding of prosumption activities and their environmental and social implications focusing both on prosumers themselves and business models facilitating prosumption. In this article, we take a business perspective on prosumption and use the stakeholder view of the firm to demonstrate how different prosumption activities influence the business models of incumbent organisations in two industrial sectors, namely energy production and personal mobility.

Keywords: prosumption, sustainable consumption and production, stakeholder approach, business model

1. Introduction

Exploring the perspectives for a sustainable society in the 21st century, Alvin Toffler argues in his book, 'The Third Wave' (Toffler, 1980) that the number of classic consumers of industrially provided goods will decline

and will be replaced by 'prosumers': people producing and consuming goods and services for their own and other's consumption (Ritzer and Jurgenson, 2010).

Since then, several definitions of prosumption surfaced and the fast-growing number of prosumers and the increasing importance of prosumption in the economy slowly started to spur scientific inquiry into the topic. In 2009 Ritzer discussed the 'age of prosumer' (Ritzer, 2009) just to be followed by others characterising prosumers and certain types of prosumption activities (see e.g., Blättel-Mink and Hellman, 2010; Collins, 2010; Comor, 2011; Humphreys and Grayson, 2008; Ritzer, 2010; Ritzer and Jurgenson, 2010).

In practice, production and consumption has been traditionally intertwined – local agricultural production providing a perfect example – until the first industrial revolution, which resulted in the widespread use of mechanized factory systems and novel organizing solutions. Successive industrial revolutions brought about the emergence of mass production, which still characterises most of the products we consume today and reduced the significance of small-scale production.

However, consumers' contribution to the economy never ceased. Ritzer (2013) in fact identifies a continuum from prosumption-as-production to prosumption-as-consumption, along which most activities can be placed stating that production and consumption have never been fully separated. "Production and consumption, at least in their pure forms devoid of prosumption, do not exist on this continuum. There is no such thing as either pure production (without at least some consumption) or pure consumption (without at least some production); the two processes always interpenetrate. In the ''middle'' of the prosumption continuum production (-as-consumption) and consumption (-as-production) are more or less evenly balanced; it is there where something approaching ''balanced'' prosumption exists" (Ritzer, 2013, p. 8).

Prosumption does not assume that production and consumption happen at the same time or same location. Over the years, a number of prosumer activities have been identified from do-it-yourself home repair (Watson and Shove, 2008), through the creation and consumption of craft products (Campbell, 2005), co-creation (Prahalad and Ramaswamy, 2004a; Prahalad and Ramaswamy, 2004b), collaborative capitalism (Cova et al., 2011), productive consumption (Laughey, 2010), etc. The concept of prosumption – coined before the age of the internet – has proved to be surprisingly useful in understanding various consumer behaviours as we experience them today, but broadening its coverage to many, hugely different activities may also lead to a loss of its explanatory power.

In the next section we introduce some of the most important types of prosumer activities, some of which have been around for longer periods, while others emerging only recently, typically with the spread of the internet.

2. Typical areas of prosumption

Producers more and more often delegate tasks to consumers, which have been traditionally part of their job, in order to reduce costs. Such prosumers are engaged in collecting their items in storehouses, checking them out on their own and shipping and setting up the products themselves. The resulting cost reduction can be shared between the producer and the consumer (Lengyel and Rechnitzer, 2004), although some see such activities as new forms of exploiting consumers (see McDonaldisation by Ritzer, 1993)

While such tasks can be a burden to some, the benefits of traditional do-it-yourself (DIY) activities usually go beyond saving financial resources. Home improvement and other similar pursuits can become a serious hobby and provide some additional income as well apart from saving on the bills.

Food production has several forms, in which production and consumption is connected (Moreira, 2020). Traditional small scale, household farming is a typical example, but newer forms such as growing spices in windows and cultivating mushrooms in garages are also spreading. Veen et al. (2021) add community gardens, the gathering of fruits in wilderness areas, beekeeping and hunting and fishing.

Another example of spreading prosumer activities is the installation of household scale power plants utilising renewable energy resources such as solar, wind and biomass energy (Kotilainen, 2020). The resulting distributed energy systems promise environmental and social benefits and may dramatically change business models prevalent in the sector already in the near future. They also turn passive consumers into active prosumers, which has important implications for the energy markets (Ellsworth-Krebs and Reid, 2016).

A new area of prosumption has been created by the fast spread of the internet and social media. As of April 2022, there were 5 billion internet users globally most of whom (4.65 billion) were also active social media users (Johnson, 2022). Internet communities do not only serve as a source of information, but ‘digital prosumers’ use the available platforms to create content – often free of charge.

Real time, uninterrupted access to the internet also created innovative business models, such as those of the sharing economy. Car and apartment sharing platforms promise a better utilisation of resources and related environmental and social benefits, and other sectors are also exploring the possibility of the sharing business model (e.g., in the job and financial markets) (Lengyel, 2017).

Customization (Salvador et al., 2020) and co-creation (Prahalad and Ramaswamy, 2004; Ranjan et al., 2021; Cui et al., 2021; Re et al., 2022) are also often seen as novel forms of prosumption, when the consumer is involved in the development stage of the product life cycle (Zhang et al., 2022). Both producers and consumers may benefit from this involvement, companies being able to collect precious information about their customers.

3. Theoretical background and method

In order to better understand the business aspects of prosumption, we take a stakeholder approach since it has a potential benefit of highlighting the changes in the roles of consumers and producers within the context of prosumption. As a practical tool, we will use the concept of business modelling, which in turn is beneficial in understanding the interrelated activities of different stakeholders and can provide insights regarding how new, innovative business models embrace the phenomenon of prosumption.

Post et al. (2002) characterizes the extended enterprise as "the nodal element within a network of interrelated stakeholders that create, sustain, and enhance its value-creating capacity". They define stakeholders as "individuals and constituencies that contribute, either voluntarily or involuntarily, to its wealth-creating capacity and activities, and who are therefore its potential beneficiaries and/or risk bearers" (Post et al., 2002, p. 8). This wealth creation is put into the centre of business modelling as value creation (see e.g., Osterwalder et al., 2005).

The stakeholder approach of the firm emphasizes the importance of the needs of various stakeholders of the firm in company decision making processes beyond its actual owners in order to achieve long term market success. The stakeholder approach implies that companies should seek ways in which to satisfy these often-diverging needs – especially of critical stakeholders – and that failing to do so may result in company failure.

Customers and users are some of the most critical stakeholders for any business organisation, thus require special attention. With the emergence of prosumption, companies selling to final customers, find that their customers take up new roles and have new ways of influencing their operations, they cease to act solely as customers. With self-service options, for example, customers deliver the job of those, formerly employed by the organisation while renewable energy producing households may completely turn away from their service providers. These – when becoming large scale – can provide serious problems to energy companies and the whole sector. Moreover, the spread of prosumption may also give birth to new sectors of industry and changes the role of other stakeholders.

In the next section we analyse two typical areas of prosumption, namely the utilisation of renewable energy sources to produce electricity for one's own consumption and the different models of the sharing economy. We will use the framework developed by Post et al. (2002) depicted in the following figure to describe the operation of the extended enterprise illustrating the position of various stakeholders in relation to the 'resource base' of the firm, its interaction with the 'industry-market' and the 'social-political arena' it operates in.

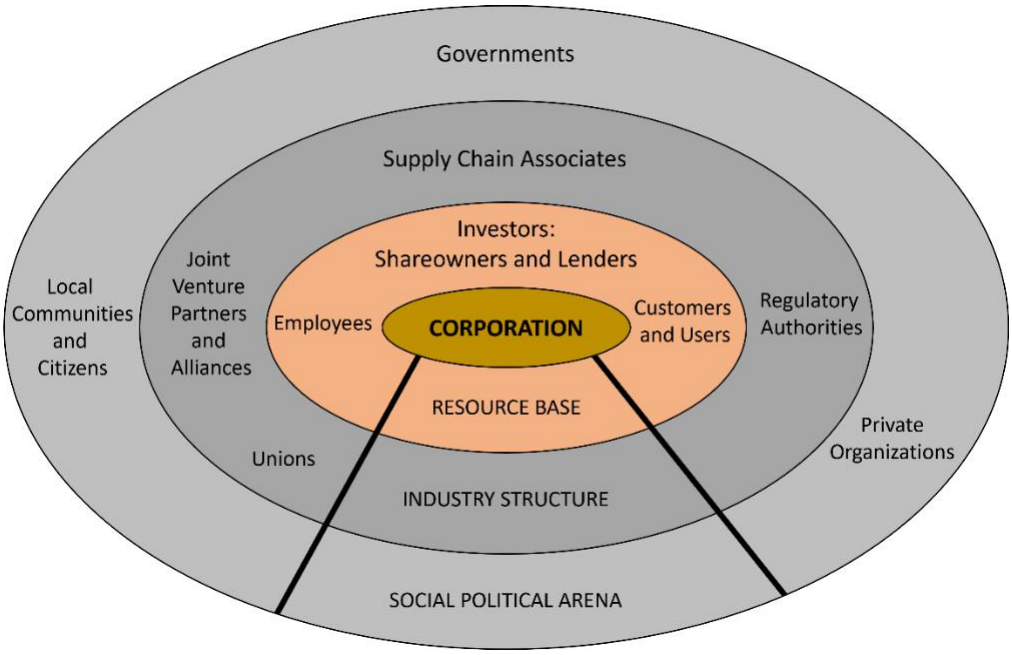

Figure 1. *The stakeholders of the firm in three dimensions (Post et al., 2002).*

According to this model, the customers of the firm constitute the resource base of the firm, along with the employees and investors, while communities form part of the social-political arena, such as other private organisation.

We will also utilise the concept of business models, defined by Magrette as stories that describe how companies operate (Magrette, 2002). According to the popular definition of Osterwalder and Pigneur, business models demonstrate how organisations create, deliver and capture value (Osterwalder and Pigneur, 2010), while from a stakeholder perspective the definition of Zott and Amit (2010) is especially useful defining business models as systems of different activities undertaken by the business organisation to meet market demand. Business models define which players (the company and its partners) undertake what activities and how these activities fit together.

The literature often identifies business models by their components. According to Barakonyi (2008) we can distinguish between the following components:

- infrastructure
- fundamental capabilities (as most significant resources)
- network of partners (with which missing capabilities can be compensated)
- consumer (at the centre of the business model)
- distribution channels and the
- financial system including the cost and income structure.

Studying the phenomena of prosumption can benefit from the concept of business models not only because it concentrates on the roles of different stakeholders and thus can describe prosumption activities, but also because the design of appropriate business models may promote sustainable ways of prosumption. We illustrate the usefulness of these concepts in the next sections by introducing how the role of stakeholders change in the case of two specific types of prosumer activities, namely household energy production and the sharing economy.

4. Household energy production as prosumption

Hall et al. (2020) describe a number of business models built around the household production of energy based on renewable resources, such as solar and wind. Many of these models build upon the support of individual households in order to promote a more sustainable, distributed energy system, which is also believed to contribute to our fight against climate change. One such system operated in the United Kingdom till 2019, within which prosumers producing electricity with the help of solar panels attached to their roofs received two types of payments: one for the net amount of energy (after subtracting their own consumption) exported to the grid (feed-in-tariff) and another payment (subsidy) to support energy production based on the total energy produced. Moreover, prosumers participating in the scheme were also charged favourable energy system usage fees.

Another typical business model utilizing renewable energy sources is the setting up and operation of energy communities, which can bring savings and extra income to a number of households spreading the costs of investment and enjoying its benefits together (e.g., owners of apartments in buildings, neighbourhoods, etc.). Such tenant electricity models operate in Germany with the name of ‘Mietstrom’, under which businesses owning such solar roof systems can sell the produced energy to the tenants without charging network fees and other taxes in the case of solar systems smaller than 100 kW.

Another model (the so-called the local energy company model) operates in Portugal, in which local communities team up to produce renewable energy, which they trade between each other through a local energy company to optimize at the local level, before they sell to external customers. Local energy charges are established by the community so that they maximise local use (Hall et al., 2020).

Apart from technological innovations in the renewables sector, such innovative business models and related financial schemes are needed to increase the share of renewable energy sources in today’s societies (Horváth and Szabó, 2018). This is not only beneficial from an environmental perspective, but also brings about more resilient energy systems.

However, all of these solutions have dramatic effects on the relationship between traditional energy producers and their stakeholders, especially those who they traditionally deemed as their customers. While it is unrealistic to assume that incumbent companies will lose their customers in the short term, local power generation already influences the stability of the electricity grid. In Hungary, for example, where the government supports household solar investments by operating a net payment system (meters are read once a year and payments are made based on the net amount of energy used), voltage anomalies and power surges already happen in neighbourhoods with high built in solar capacity. Yet, prosumers benefiting from this system do not contribute to the maintenance of the national electricity grid and the mismatch between supply and demand will require investments into storage facilities by the traditional players of the sector.

With the spread of household energy consumption, the traditional consumer and his/her behaviour will change considerably. While electricity markets are characterised by daily and seasonal fluctuations, the overall household demand of electricity can be forecasted and planned rather precisely for even longer periods, much better than in other market segments. The number of households and their energy consumption patterns change only over longer periods of time, which stabilises the markets. On the other hand, shifts in the energy infrastructure also take long time to manifest, thus the development of markets can maintain a long-term balance.

With the fast spread of household energy production, some of this stability is lost. Producers should catch up with the fast growth of home electricity production by preparing and restructuring national energy systems, which will be needed even if all households could fully provide for their own electricity consumption. Thus, the value created, the main activities and the income structure – and ultimately the entire business model – of traditional energy companies should be reconsidered with a higher emphasis on the provision of infrastructure and storage services.

Household producers of electricity do often also replace their demand for natural gas and/or oil by electricity, for example by turning to electric heating and electric personal vehicles. This will have a significant impact on the companies of the oil and gas sector and their business models.

Prosumers also often become more aware of the products they produce and consume, which may especially happen in the electricity sector, where many of the traditional consumers do not have a good understanding of either how the electricity system operates or how much they pay for the received services. This is in fact one of the main barriers of reducing energy consumption at the household level. Consumers turning into prosumers and furnished with the appropriate tools (e.g., mobile applications), however, become more aware of their energy use patterns and their implications compared to their traditional consumer counterparts.

While local communities have always been one of the stakeholder groups influencing company operations, customers forming energy communities and using local energy service providers make them even more

important. Local communities have always played the role of customers through buying energy to provide local services, but now private customers also turn into communities, which are more aware of energy matters and conscious about their choices.

It is not only customers/communities and their behaviour that changes with the emergence of prosumption in the energy sector, but other private organisations also appear on the market, which provide permitting, consulting and installation services. Financial institutions such as banks and insurance companies also offer new, targeted products to homeowners and communities. While some traditional energy providers also started to offer similar services, in many markets the demand for solar installations resulted in a boom of these new service providers, creating new stakeholders for traditional electricity producers.

5. Prosumption in the sharing economy

The development of the information technology and the fast spread of the internet provides opportunities for a number of innovative business models. One prominent example is provided by the companies of the sharing economy, which promise parallel economic, environmental and social benefits, although assessing their overall impact is often difficult and raises methodological issues. With the fast spreading of sharing economy businesses, several distinct types of business models based on resource sharing emerged, which differ considerably from each other (Soltész and Zilahy, 2020). Many of the sharing economy businesses, however, provide a platform for different types of prosumers: prosumers can use home sharing applications to rent their apartments on a short-term basis and can lend their cars and other valuable appliances to others for a fee or free of charge.

The various sharing economy business models may be implemented by the incumbent businesses of the tourism, mobility and other relevant sectors or by newcomers to the industry (start-ups). In both cases, the traditional relationships of businesses and their stakeholders change radically compared to traditional business models.

A change in the role of customers is indicated by the use of the more appropriate term ‘users’ who themselves can take a number of different roles. Users of drive sharing platforms (e.g., BlaBlaCar) can act either as passengers or drivers (or both). The means of mobility (e.g., a car), which formed the value proposition of traditional businesses is replaced by the opportunity to connect offered by platform operators.

In the peer-to-peer sharing economy business models (P2P) users often interact more closely with other users than the actual platform provider, which coordinates activities from the background. In business-to-peer (B2P)

models the service provider still plays a central role, but instead of providing users with physical assets (i.e., cars), they become service providers.

Service oriented business models in general promise a number of economic and sustainability advantages, which is warranted by a shift in the underlying interests of the most important players. While the income of traditional producers is attached to the number of products and related services sold (and are thus interested in frequent repeated purchases and the provision of expensive services), in service-based business models service providers are interested in utilising durable products, which they can use to provide high quality services for a long period.

However, users of the sharing economy do not embody only the traditional customers, but also employees as it is apparent in the case of the access economy (e.g., Uber). While providing additional income to such 'employees', a number of social issues are raised by the operation of these businesses, which may take advantage of their users (e.g., by not providing social security, etc.).

6. Conclusions

Post et al. (2002) identifies an organisations' role towards their customers/users to include: building good reputation and brand loyalty; urging repeated purchase; collaborating in problem-solving and developing new products and services. While some of these roles will be still relevant with the emergence of prosumers, we demonstrated that changes in the business models employed are inevitable. Prosumers do not only act as consumer, but also as suppliers (e.g., renewable energy) and/or employees (e.g., in the access economy). The tools developed by traditional companies to deal with these stakeholders may or may not apply in the case of prosumers. In order to achieve market success, companies actively manage their supply chains: cooperate for better products and lower costs. In the case of larger organisations this is supported by their market power. However, if traditional suppliers are replaced by thousands of prosumers, such an optimisation may not be possible or should take a different form.

Similarly, replacing employees by prosumers may offer a number of benefits (mainly by reducing costs), but may also reduce the control of companies over their workforce. Prosumption also contributes to the formation of new stakeholders (e.g., private organisations), which should be dealt with through conscious stakeholder management and the change in the role of other traditional stakeholders, e.g., communities and regulatory authorities.

These changes resulted by the emergence of the prosumer economy challenge mainly incumbent companies, which utilise traditional business models. In contrast to technological innovation where large, established organisations may have an advantage because of their significant R&D infrastructure and resources available,

they may be at a disadvantage when business model innovation becomes necessary. Beliefs of how companies in a certain industry should operate and inflexible organisational structures may mean that newcomers can take over the lead.

Our analysis showed that taking a stakeholder approach to understand how the emerging phenomena of prosumption affects business operations is a valuable contribution to this relatively new area of management science. However, our current analysis is only a first step, which should be complemented by empirical research of both prosumer behaviour and changing company practices.

Abstract

Sustainable consumption is gaining scholarly attention as it has become an essential aspect of designing and implementing national and international policy. But the emergence of environmental concerns has not been attributed to an increase in the consumption of sustainable fashion (textile) products. The review of the literature regarding fashion consumption shows that most studies focus on consumers' initial purchase willingness and behaviour for fashion products. As a result, to complement previous research, this paper aims to identify and categorize the drivers of consumers' post-purchase willingness and behaviour toward new and second-hand fashion products.

The literature on sustainable consumption has grown dramatically, but most have focused on initial purchase decisions. This study went beyond the purchase decision and aims at the post-purchase decision for different types of fashion products. It focuses on consumers' willingness and behaviour to reuse, repair, recycle and repurchase new and second-hand fashion (clothing) products. It compares consumers' post- purchase behaviour of new and second-hand fashion. To complement these research findings, our study attempted to reveal consumers' post-purchase behaviour, asking the following questions: what factors influence post-purchase behaviour towards reuse, repair, and recycling of fashion products? What factors influence consumers' post-purchase behaviour towards the repurchase of fashion products? We developed our research model with the theory of planned behaviour as a background because consumers' attitudes, subjective norms, and perceived behavioural control considerably impact post-purchase willingness and behaviour of fashion products.

The study's primary purpose was to gain a deeper understanding of how buyers dispose of clothing items and how they respond after purchasing second-hand fashion products. However, it later focused on both new and used textiles to better understand initial purchase behaviour and second-hand product purchase behaviour. The research used both qualitative and quantitative research methods. We have already gone through the qualitative research where second-hand fashion store owners and consumers were interviewed regarding their purchase behaviour patterns.

Based on this, a large-scale questionnaire survey of new and second-hand fashion consumers has been carried out. We surveyed the post-purchase behaviour of 490 individuals through telephone calls. The questionnaire survey used a non-random sampling method to reach a representative group of consumers of Budapest, Hungary. Data has been analysed using multi-dimensional statistical methods to uncover patterns of post-purchase behaviour. The research results will enable us to understand better the sustainability implications of the new and second-hand fashion market and form suggestions for policymaking relating to this vital sector.

Keywords: Sustainable consumption, fast fashion, second-hand fashion products, post-purchase behaviour, textile fashion products.

1. Introduction

In recent years, the literature on sustainable consumption has exploded. Consequently, sustainable consumption has become an essential component of national policy development and implementation. The subjects of this study were consumer attitudes and behaviour toward post-purchase reuse, repair, recycling, and repurchase of new and used fashion (clothing) products. As a result, the research study focused on post-purchase decisions for numerous forms of fashion products rather than purchase decisions. It analysed customers' post-purchase behaviour for new and used fashion and influenced their post-purchase behaviour for reuse, repair, recycling, and repurchase of fashion items.

In the last three decades, experts have paid close attention to the concept of sustainable development. Sustainable consumption and production are vital elements of sustainable development, as they require firms and consumers to adopt sustainable behavioural patterns. The World Commission on Environment and Development (1987) defined sustainable development as meeting the current requirements without damaging future generations' capacity to achieve their own needs. It forms a basis for executing social and environmental policies and activities. Researchers are constantly considering sustainability on a conceptual level, whereas corporations and policymakers deal with sustainability issues on a pragmatic level. Environmentally friendly consumption is a significant component of long-term sustainability. As a result, both consumers and businesses need to pay greater attention to environmental protection to ensure long-term sustainability.

Clothing is one of the essential components of a human's life. As a result, one of the most important sustainable and green consumer product types is sustainable fashion. However, due to the apparent growing usage of textiles and the consequent environmental, moral, and societal issues, sustainable apparel consumption is becoming contentious. During 1975, for example, 34 million metric tons of apparel fibres were produced

globally. This number will have more than tripled before 2020, exceeding 109 million metric tons, reaching 146 million metric tons expected before 2030 (Esbeih et al. 2021). According to a study by Gilg, Barr and Ford (2005), consumers expect moral, environmentally friendly, and socially conscious items. Green apparel is durable, according to Chan and Wong (2012), since it incorporates organic elements and fibres and promotes ethical practices that conserve the environment for future generations. Niinimäki (2010) revealed that ethical beliefs and attitudes to shopping behaviour are vital motives for purchasing green apparel. Such a moral attitude increases the product's worth, resulting in prolonged product longevity, more remarkable results, and a shorter fashion loop. Another way of approaching understanding the meaning of modern consumerism, apparel consumption, and consumers purchasing preferences is to examine the moral consumer's attitude in the apparel sector. They evaluated green consumption from the perspective of distinctiveness and cognitive qualities such as ethical commitment. The environmental factor of sustainable consumption and production is related to sustainable fashion (Lundblad and Davies 2016). Furthermore, sustainable fashion encompasses a wide spectrum of socially accountable considerations in the production and use of clothing (Lee et al. 2012).

In recent times, scientific work in the apparel industry has emphasized sustainability. However, consumption and production in the fashion business are unsustainable (Connell 2010). As a result, fashion and clothing item disposal has dramatic negative impacts (Kant 2011), and waste minimization can be obtained through reuse (Geissdoerfer et al. 2017). Furthermore, "fast fashion changes" are a societal issue that has led to the trash and environmental disasters (Birtwistle and Moore 2007). Even the apparel business has contributed to the spread of home garbage. For example, according to "China Water Risk," Industries produce over 65 per cent of the world's enormous apparel. As a result, identifying a solution is necessary, as decreasing fabric and apparel usage cannot be the primary solution to pollution challenges. Recycling, redesigning and renovating new apparel to extend the product's useful life span appear to indicate environmentally sustainable apparel products and discarded modes of behaviour that promote sustainability. The use of second-hand apparel products is becoming more popular every year, and the largest market for second-hand apparel is expected to nearly or more in the future years (Herjanto, Scheller- Sampson, and Erickson 2016). As per Farrant, Olsen and Wangel (2010), reused clothing is also correlated with lowering the amount of thrown-away garments into the garbage and lowering environmental pollution. Aside from that, clothing renting and exchanging are becoming more popular in offering customers second- hand consumers' buying options (Albinsson and Perera 2009). So this research focuses on the post-purchase behaviour of consumers of new and second-hand fashion products that may lead consumers to repurchase fashion products that can be reused, repaired, and recycled, minimising waste of clothing products.

Much research has already concentrated primarily on consumer behaviour to improve long-term behavioural patterns (Kronrod, Grinstein, and Wathieu 2012; Lilley 2009; Young et al. 2010). But the researchers also

argue that several studies on second-hand clothing are limited and not more like other sectors (Na'amneh and Al Husban 2012). So by examining consumers' post-purchase behaviour of second- hand fashion products, it can be possible to know how consumers can be motivated, encouraged, and facilitate sustainable lifestyles in the textile (clothing) sector. Moreover, a phenomenon of new and second- hand fashion products was explored that provides a review of consumers' post-purchase behavioural intentions towards repair, reuse, recycling and repurchase of fashion products which will lead the researchers in their future research directions. Because reusing apparel is linked to a decrease in the cost of discarded clothing in landfills and a pollution reduction (Farrant et al. 2010). Besides that, clothes rental and swapping have become increasingly common ways for buyers to buy used apparel (Albinsson and Perera 2009). Therefore, this study focuses on consumers' post-purchase behaviour of new and used fashion items, which may also result in customers repurchasing clothing items that can be recycled, repaired, and reused, reducing textile trash.

To better understand consumer behaviour patterns, this study focused on the post-purchase behaviour of new and used fashion products. The method through which purchasers use goods and services and assess their efficiency is called post-purchase behaviour (Assael 2005). At the post-purchase stage, customers consider whether they are happy with the product, which impacts their future choices. Consumer happiness is linked to repeat purchases. Customers' shopping for fashion (clothing) products is based on three factors: individual, situational, and product qualities (Bianchi and Birtwistle 2012; Ha-Brookshire and Hodges 2009). (Gunnells, Hale and Hale, 2009)Individual characteristics include behavioural, emotional, and demographic characteristics (Gunnells, Hale, and Hale 2009). Furthermore, human traits such as motivation, mood, self-concept, and confidence are examined. Finally, demographic factors such as age and gender are cognitive elements that influence customers' decisions to buy fashion apparel (Bianchi and Birtwistle 2012; Felix, Asuamah, and Darkwa 2013).

According to Machado *et al. (*2019), various variables influence buyers' post-purchase behaviour for new and used apparel products. Customers who buy apparel are influenced by uniqueness and style accessibility because they are impressionable. Another aspect, on the other hand, determines the post-purchase behaviour of clothing products for consumers. Social behaviour contributes to the long-term use of apparel products (Kong et al. 2016). When picking which stores to go to and what to acquire, buyers are significantly impacted by social considerations when deciding which stores to go. The theory of planned behaviour was applied to various product areas, including organic food studies (Arvola et al. 2008). The idea of planned behaviour by Ajzen (1991) is frequently employed to anticipate consumer behaviour, implying that subjective norms account for consumer behaviour. Schaller and Malhotra (2015) wrote a book that used planned behaviour theory to conduct a survey in which attitudes, personal criteria, and perceived behavioural control were all significant factors. The study's outcomes are relevant to the design of a decision-making

process and behavioural modifications.

2. Method

2.1 Research design

The modern clothing industry has progressed well beyond simply meeting basic physiological and psychological needs. The emergence of fast fashion has drastically altered the social and cultural meaning of clothing. As a result, the focus of this research was on sustainable new and second-hand fashion in the clothing industry. Following a literature review, this study discovered that social and personal norms are connected and impact behavioural intentions for buying new and second-hand fashion products that can be reused, repaired, recycled, and repurchased. Furthermore, environmentally conscious consumers who are more knowledgeable and aware of environmental benefits react favourably at the post-purchase stage and consider the issues of new and second-hand clothing repair, reuse, repurchase, and recycling issues. According to Yan, Bae and Xu (2015), second-hand garment buyers are environmentally aware and buy recycled clothing to support sustainable consumption. Second-hand clothing is becoming highly widespread and the fastest growing fashion industry, also regarded as an environmentally friendly consumption choice. So it is necessary to investigate more the researchers to establish business policy. After reviewing the relevant literature and identifying research gaps, we developed a research model based on this study.

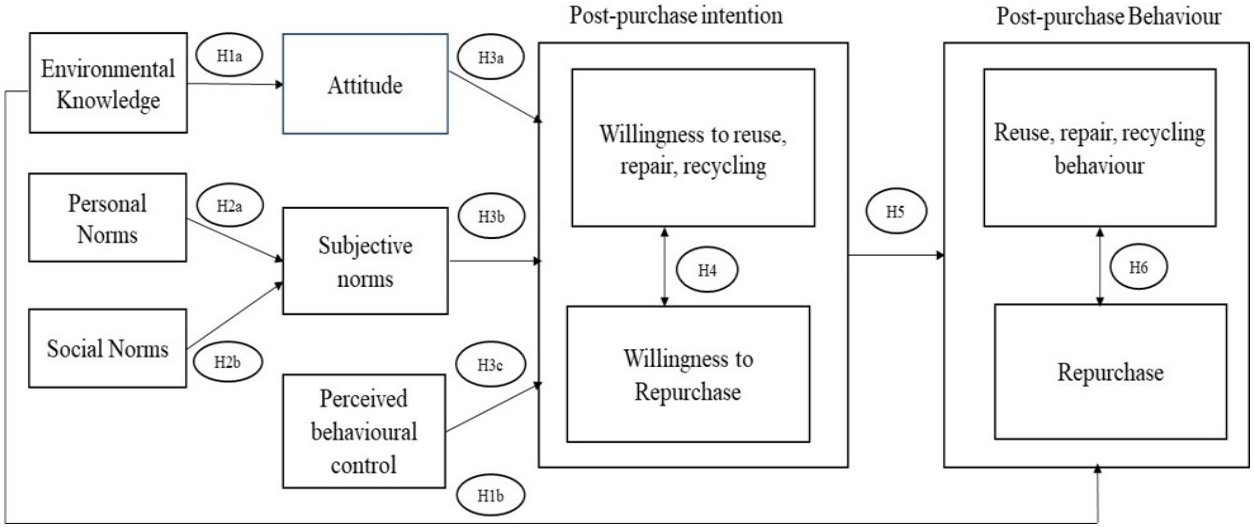

Figure 1. Research model, Source: Own edition.

After a review of literature, it was found that it is essential to investigate the factors that influence the consumers' post-purchase behaviour and intentions to repair, reuse, repurchase, and recycle new and second-hand fashion products. Thus some of the research questions were found to get answers from this research

work. The research questions are: what factors influence consumers post-purchase behaviour towards reuse, repair, recycling of fashion products? What factors influence consumers post-purchase behaviour towards the repurchase of fashion products? Based on these research questions, theory of planned behaviour and related literature and research model, we have developed some hypotheses, which are:

- H1a: Environmental knowledge positively affects consumers' attitudes.
- H1b: Environmental knowledge positively impacts consumers post-purchase behaviour towards reuse, recycling, repair and repurchase of fashion products.
- H2a: Personal norms have positive impacts on subjective norms. H2b: Social norms have positive impacts on subjective norms.
- H3a: Attitude positively impacts consumers' post-purchase intentions for reuse, recycling, repair and repurchase of fashion products.
- H3b: Subjective norms positively affect consumers' post-purchase intentions for reuse, recycling, repair, and repurchase fashion products.
- H3c: Perceived behavioural control positively affects consumers' post-purchase intentions for reuse, recycling, repair, and repurchase fashion products.
- H4: Consumers' willingness to reuse, repair, recycling, and willingness to repurchase are interconnected.
- H5: Consumers' willingness to reuse, repair, recycling, and willingness to repurchase have positive impacts on consumers' post-purchase behaviour towards reuse, recycle, repair and repurchase of fashion products.
- H6: Consumers post-purchase behaviour to reuse, repair, recycling and repurchase are interconnected. But we have worked on H1a, H1b, H3a, H3b, H3c and H5.

2.2. Data collection

We followed multiple methodologies (qualitative-quantitative approach) known as triangulation for conducting this study. Triangulation is described as incorporating two or even more philosophies, data collection methods, processes, or investigations into a single analysis of a specific concept. A researcher can interview people of differing perspectives and vastly different levels of authority, like high-level management staff and position executives in the same company (Denzin 2007). Triangulation is significant in research, including interviews to get a complete view of the current situation and problems (Davies 2001). At first, we conducted interviews of the major stakeholders and consumers of second-hand fashion products and to determine the research questions concerning post-purchase behaviour and disposition of fashion products. Then we our department hired a professional survey company to conduct telephone interview of 490 consumers who buy new and second-hand fashion clothing. The data collection methods were as follows-

Qualitative Research

In social science, qualitative research considers various problems with the interview. According to

researchers, qualitative is the reality generated interactively and then becomes meaningful subjectively (Hopf 2004). Initially, we conducted consumer focus groups and interviews to understand the critical themes relating to fashion consumption patterns and the disposition of second-hand fashion products. We validated the qualitative research results and evaluated the intensity of repair, reuse, or recycling of second- hand fashion products. Furthermore, we intended to set our research goal and conduct a survey questionnaire to do quantitative analysis based on understanding the problems and limitations from the focus group interviews with the major stakeholders and consumers of second-hand fashion products. We did this so that the quantitative survey questionnaire variables would be valid, reliable, and valuable for our research. This preliminary focus group interview revealed consumers' lack of understanding of how their behaviour affects the environment and how cloth trash and clothing consumption can be made entirely sustainable.

As a representative city of Europe, we chose Budapest as the sample area for our research. Budapest has 23 districts, 16 of which are on the Pest side.

As a result, we focused on the Pest side and preferred various second-hand fashion stores in some of the largest districts: V, VII, and VIII. First, we interviewed the significant stakeholders directly related to second-hand fashion stores such as Hada, Cream, and Vintage shops. We interviewed the shop's managers and a few of its employees. We visited ten stores, but stakeholders from eight were able to provide information because the managers of the other two stores were busy with a new collection of stocks and were unwilling to participate in the interview. As a result, we conducted interviews with eight managers and four staff of second-hand fashion stores. Then we narrowed our focus to consultations with customers of second-hand fashion products. We interviewed ten consumers who had bought clothes at second-hand fashion stores. On the other hand, the professional survey company conducted the telephone interview by following the non-random sampling method.

Quantitative Research

To validate the research hypotheses, research was conducted via questionnaires distributed to a survey of responsible consumers in Budapest. After receiving the responses, we analysed the data to see if the reliability of the answers was significant. The population of Budapest in 2021 is now estimated to be 1,771,865. Budapest has a total land area of 525.2 square kilometres. With roughly 1.77 million citizens, the population density is approximately 3,351 persons per square kilometre (Source: World Urbanization Prospects - United Nations population estimates and projections of major Urban Agglomerations). So it was challenging to collect data from all types of consumers of Budapest.

After reviewing the literature, some variables from the research model were utilised in developing the questionnaire to collect data through telephone interview. The variables are social norms, personal norms,

repair, reuse and recycling, environmental knowledge and awareness and product attributes. In addition, age, gender, level of education, employment status, monthly income, and shopping frequency have all been considered demographic variables. A 5-point and 7-point Likert scale was also used in the survey questions to anticipate potential consumers' behavioural intentions.

2.3 Data Analysis

The frequency, EFA (exploratory factor analysis), and reliability have been examined using SPSS 26.0.

3. Result

3.1 Results from the survey

We followed snowball sampling in the interview method to collect data from the major stakeholders of the second-hand fashion stores. Snowball sampling is a technique of randomising a sample of participants from a known population. Participants who are not in the randomly selected model but are instead identified by someone from the first phase. In the very first phase, participants are then asked to give the name of the various individuals (Goodman 1961). The profile of the respondents from major stakeholders is as follows-

Table 1: Profile of the respondents of significant stakeholders from the interview

Participant (P) numbers	Gender	Age range
Managers		
P1, P4, P5	Female	25-40
P2, P3, P7, P8	Female	30-45
P6	Male	25-40
Staffs		
P9, P12	Female	25-40
P10, P11	Male	30-45

Table 2: Profile of the respondent (consumers) from the interview

Participants of Consumers (C)	Gender	Age	Income range	Marital status	Occupation
C1	Female	20-30	$600-$800	Unmarried	Student
C2	Female	31-45	$0-$500	Married	Housewife
C3	Female	45-above	$0-$500	Divorced	Housewife
C4	Male	31-45	$600-$800	Married	Job
C5	Male	20-30	$0-$500	Unmarried	Student
C6	Female	20-30	$600-$800	Unmarried	Student
C7	Female	31-45	$600-$800	Married	Job
C8	Male	31-45	$1300-$Above	Married	Business
C9	Female	20-30	$600-$800	Unmarried	Job
C10	Male	20-30	$600-$800	Unmarried	Student

Table 3: Coding of the answers of the major stakeholders and consumers from the interview

Questions	Answers
From major stakeholders:	
What factors influence consumers repurchase of second-hand fashion products?	Cheap, reasonable, diversity of products, branded products at a low price,
What types of consumers buy it more? (By Gender and age)	All types but mostly the females, teenagers. In age mostly from 20-80.
What types of strategies do second-hand fashion stores follow to repair, reuse, and recycle second- hand fashion products?	Discount, everyday services, environmental protection, diversification, associations of products, understanding customers' demands, repairing products to make usable, and recycling products to minimize waste.
From consumers	
What do you act normally when the clothing products are damaged?	Throw, repair and reuse, the gift to family members and relatives, sell to second-hand fashion stores, donate to the voluntary organization and low-income people,
Why do you buy second-hand fashion (clothing) products?	Cheap, helpful to maintain social status, branded products availability, environmentally beneficial,
What factors influence your post-purchase intentions when you buy second-hand fashion products?	Opportunity to get high quality and branded products at a low budget can be maintained different styles, social and financial balance, saving money and controlling consumption more.
What are the reasons for your negative post- purchase behaviour of second-hand fashion products?	Non-returnable option, no warranty, quality and durability issues,

Almost all the eight managers and four staff of the second-hand fashion stores stated that consumers purchase second fashion products because they are affordable. The managers of the second-hand fashion stores told that all ages of consumers demand buying products from there. Nowadays, there is much demand for children's dress as they grow up very quickly and their dresses are more expensive. But mainly by the age range 20-80 years of consumers are comparatively other ages. They believe they contribute to sustainable consumption

as they provide everyday services to consumers who are providing consumers to fulfil their needs of clothing at a reasonable price. Moreover, they said they keep the clothes' categories in different sections to make the shopping easy. They have many stories in other places to make it available to all consumers. For example, the manager of Hada in Corvin plaza said that they had had 88 stores in the whole of Hungary for 25 years that are operating services of second-hand fashion clothing for consumers as part of sustainable production and consumption. Even their logo of the name indicates that it is secure and states that they are providing environmental protections. The other stakeholders said they focus on repair, reuse, and recycling strategies to provide consumers with better services. Even though they have separate marketing departments that handle the consumers' issues, they considerably consider consumers' reviews and try to correct services as per that. But they believed that still there is a lack of consumers' awareness about the environmental benefits of using second-hand fashion products; instead, they are more concerned about price and brand. However, they think yet they must lack ecological knowledge. Still, consumers' buying habits as positive post-purchase behaviour may have a long-term positive impact on sustainable consumption that will help to reduce waste in the textile industry.

From the side of consumers, the respondents were interviewed with some questions regarding their purchase and post-purchase intentions towards second-hand fashion products and whether they were concerned about recycling and minimisation of waste. We took interviews first with a general question like, what do they do with consequences if they are damaged or long? Why do they buy second-hand fashion products? Moreover, we tried to determine the influencing factors on their positive and negative post- purchase behaviour. In the above figure, we have coded the answers in table-VI. They have said that second- hand fashion stores can get high-quality products with a low budget, which is the main influential factor for positive post-purchase behaviour. Consumers recognise that they can purchase higher-quality, longer- lasting goods at lower prices than the local market. Even by this, they can contribute to resource utilisation as there is resource scarcity and local stores sell low-quality products at a higher price (Roux 2006). Moreover, they think that purchasing second-hand fashion products is helpful to minimise waste of the environment. According to research, the acquisition of second-hand clothing is connected to belonging because social relationships support the growing intentions with the thinking about environmental benefits (Guiot and Roux 2010).

3.2 Results of the telephone interviews

Table 4: Descriptive statistics

Attributes	Category	Frequency	Percentage (%)
Gender	Male	219	44.7
	Female	271	55.3
Monthly Income	Under 50 000 forints	8	1.6
	50 001-100 000 forints	35	7.1
	100 001-150 000 forints	88	18.0
	150 001-200 000 forints	97	19.8
	200 001-250 000 forints	62	12.7
	250 001-300 000 forints	47	9.6
	300 001-350 000 forints	28	5.7
	350 001-400 000 forints	14	2.9
	400 000 forint- above Do not	61	12.4
	know / do not answer	50	10.2
Age	Under 16	0	O
	16-29 Years	107	21.8
	30-44 Years	140	28.6
	45-59 Years	103	21.0
	60 Years- Over	140	28.6

The table 2 and figure 2 show that majority of the participants were female (55.3%) representing 271 participants while the remaining was male (44.7%) representing 219 participants. Here we can see that female participants are a bit more than male participants. Moreover, table 3 also shows the descriptive statistics of income statements of the participants. The table 3 and figure 3 demonstrate that the more percentage was in the income ratio between the 150001 to 200000 forints which is 97 participants' income. The other majority of percentage was 88 with representing the 18.0%, 62 participants with representing 12.7% and so on. But the lowest percentage of income was 1.6 of 8 participants.

The table 2 also show the descriptive statistics of age range. The same number of participants was in the age range of 30-40 and 60-over. In both range the number of participants were total of 140, respectively. Among the total 490 participants 107 participants were from the age range of 16-29 years old whereas 103 participants

were in the range of 45-59 years age.

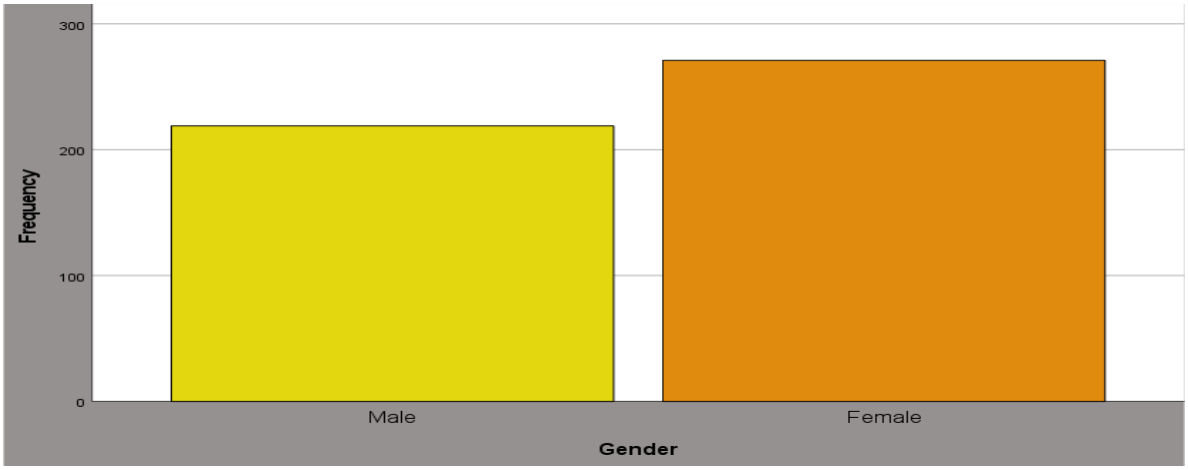

Figure 2: Frequency distribution of gender

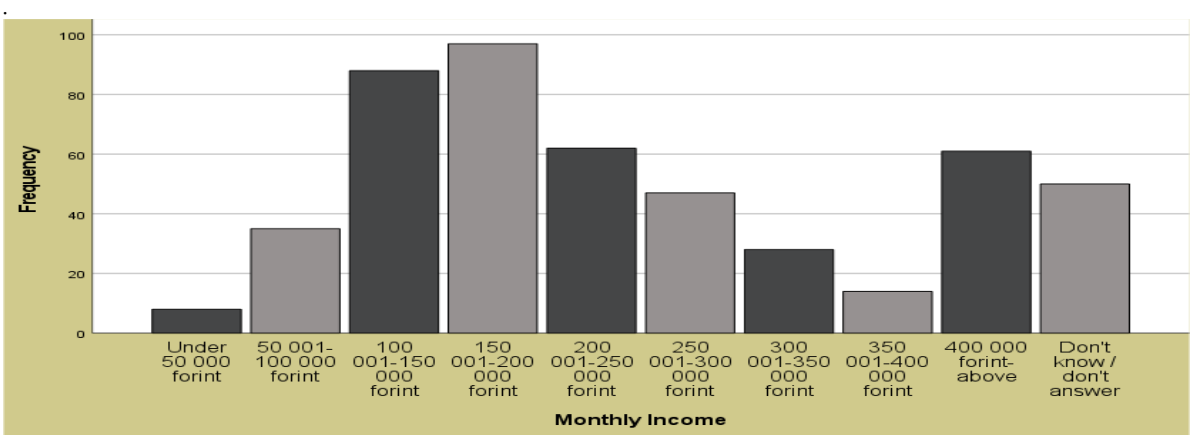

Figure 3: Frequency distribution of monthly income

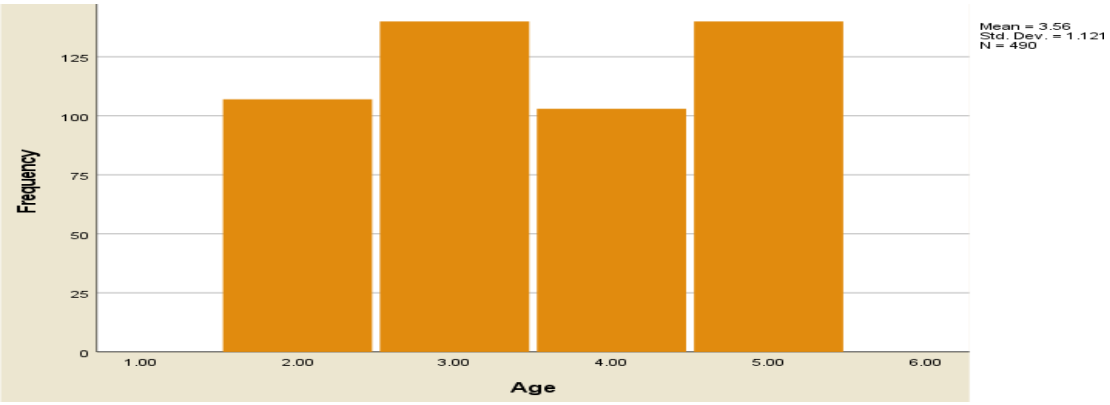

Figure 4: Frequency distribution of the age

The figure 4 states that the age distribution is significant enough to present. The mean and standard deviation are satisfactory. Most of the respondents were neutral because the mean score is 3.56 with standard deviation 1.121.

Table 5: Reliability analysis of each variable

Construct	Items	Cronbach's Alpha
Environmental Knowledge (EK)	EK1- Environmental problems are among the most important problems of our age.	.668
	EK2- The fashion industry is one of the most polluting industries regarding water pollution.	
	EK3- The production of fashion products creates social problems.	
	EK4- Fashion product producers cannot solve the environmental and social problems of the industry alone.	
	EK5- Changing consumer behaviour is an important element of solving environmental problems.	
Attitude (ATT)	ATT1- Buying too many fashion (clothing) products harms the environment.	.717
	ATT2- Companies should produce longer-lasting fashion products	
	ATT3- Fashion companies should offer repair services.	
	ATT4- By repairing and reusing fashion products the burden on the environment can be reduced.	

	ATT5- I believe that purchasing second-hand fashion products is good for the environment.	
	ATT6- Giving away fashion products, which I do not need anymore, gives me a good feeling.	
	ATT7- By selling/swapping my old fashion products I can help somebody else.	
	ATT8- Purchasing fashion products that can be used for a long period, can be repaired or recycled is satisfactory.	
Subjective norms (SN)	SN1- My friends consider environmental issues when purchasing fashion products.	.766
	SN2- Many of my friends buy fashion products in second-hand fashion stores.	
	SN3- It is trendy to shop in second-hand fashion stores.	
	SN4- My friends use their fashion products for a long time and repair them when possible.	
	SN5- If I repair and use my fashion products for a long time, most people who are important to me agree with my decision.	
	SN6- It is trendy to repair and use clothes for a long time.	
	SN7- It is common practice in my family that we pass clothing items to each other if we do not need them anymore.	
	SN8- I know many people, who give away their fashion products to others when they do not need them anymore.	
	SN9- I know many people, who sell their fashion products to others when they do not need them anymore.	
Perceived behavioral control (PBC)	PBC1- I always try to purchase fashion products that I can use for a long time and can be repaired if needed.	.662
	PBC2- If it were entirely up to me, I am confident that I will repurchase fashion products that can be used for a long time and can be repaired and recycled	
	PBC3- I feel that purchasing fashion products that can be used for a long time, can repair, and are recycled is totally within my control.	

	PBC4- In the future, it is entirely up to me whether or not I repurchase fashion products that can be used for a long time, repaired, and recycled.	
Purchase behaviour (PB)	PB1- I often purchase fashion products that are made of environmentally friendly materials.	.861
	PB2- I often purchase fashion products that are made of recycled materials	
	PB3- I often purchase fashion products that were manufactured responsibly	
	PB4- I often purchase fashion products that can be used for a long time	
	PB5- I often purchase fashion products that can be repaired	
	PB6- I often purchase fashion products that can be recycled	
Post-purchase intention (PPI)	PPI1- In the future, I intend to buy fashion products that can be used for a long period of time.	.739
	PPI2- In the future, I plan to buy fashion products that can be repaired.	
	PPI3- In the future, I will buy fashion products that can be recycled.	
	PPI4- I intend to buy clothing products less frequently in the future.	
	PPI5- I plan to use fashion products for a long period of time after purchase.	
	PPI6- I intend to give away the fashion products that I do not need to others, who can still use them.	
	PPI7- I plan to sell fashion products, which I do not need anymore.	

	PPI8- I intend to repair fashion products after purchasing.	
	PPI9- I intend to select fashion products and take them to recycle facilities/collection points.	
Post-purchase behaviour (PPB)	PPB1- I keep using fashion products as long as I can	.517
	PPB2- I reuse my outdated/used/unwanted clothing products for other purposes	
	PPB3- I give away my outdated/used/unwanted clothing products to my family members and friends	
	PPB4- I use my old garments for crafts or sewing purposes	
	PPB5- I donate my clothes to charity	
	PPB6- I often repair clothes if they are damaged and use them again	
	PPB7- When I repair my clothes, I do it because: o I like them and I get attached to them o I want to save money o I want to reduce waste o For other reasons:……	
	PPB8- I often keep my clothes for several years even though I do not use them anymore	
	PPB9- If a clothing product cannot be used anymore, I put it in the bin	
	PPB10- If a clothing product is not suitable for further use, I take it to a recycling facility	
	PPB11- If I am satisfied with a particular product, I will search for the same brand/producer again	
	PPB12- If I am satisfied with a particular product, I will continue shopping in the same store	

The table 5 shows the reliability test of each variables. There are 7 variables in the analysis with different number of items. There are 5 items in the first variable which is environmental knowledge whose Cronbach's Alpha is .668. Normally, if the Cronbach's Alpha value is .70 or greater than that then there is no problem with the items. But if there are less than 10 items then it should be more than .5. We can see that there are 8 items in the variable Environmental knowledge and Cronbach's Alpha is .630. So, we do not have any problem with the instrument to continue with our research. We can say the same with perceived behavioural control but in the other three variables which are attitude, subjective norms and post-purchase intention the Cronbach's Alpha is .717, .766 and .739 respectively which is quite significant.

So, we can go further with this research. But in the last variable (post-purchase behaviour) there are more than 10 items and the Cronbach's Alpha is .517 which is not significant. So we need to focus on each item and make the variable consistent to go for the further research.

Table 6- Reliability test of each items of PPI and PPB

Items	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted
PPI1- In the future, I intend to buy fashion products that can be used for a long period of time.	.57 . 62	.70
PPI2- In the future, I plan to buy fashion products that can be repaired.	.56	.78
PPI3- In the future, I will buy fashion products that can be recycled.	.23	.70
PPI4- I intend to buy clothing products less frequently in the future.	.42	.75
PPI5- I plan to use fashion products for a long period of time after purchasing.	.40	.72
PPI6- I intend to give away the fashion products that I do not need to others, who can still use them.	.20	.72
PPI7- I plan to sell fashion products, which I do not need any more.	.56	.77
PPI8- I intend to repair fashion products after purchasing.	.38	.70
PPI9- I intend to select fashion products and take them to recycling facilities/collection points.		.72

PPB1- I keep using fashion products as long as I can	.18	.50
PPB2- I reuse my outdated/used/unwanted clothing products for other purposes	.27	.48
PPB3- I give away my outdated/used/unwanted clothing products to my family members and friends	.30	.47
PPB4- I use my old garments for crafts or sewing purposes PPB5-	.28	.47
I donate my clothes to charity	.28	.47
PPB6- I often repair clothes if they are damaged and use them again	.30	.47
PPB7- I often repair my clothes if they get damaged and keep using them	.24	.48
PPB8- I often keep my clothes for several years even though I do not use them any more	.10	.52
PPB9- If a clothing product cannot be used any more, I put it in the bin	-.17	.59
PPB10- If a clothing product is not suitable for further use, I take it to a recycling facility	.26	.48
PPB11- If I am satisfied with a particular product, I will search for the same brand/producer again	.21	.49
PPB12- If I am satisfied with a particular product, I will continue shopping in the same store	.27	.49

The table 6 shows the reliability test of each item of the PPI and PPB from we can see the Cronbach's Alpha is significant in all the items of PPI because all are .70 and greater than that. On the other hand the Cronbach Alpha in the items of PPB is not so much significance.

We analysed correlation matrix also with some variables. Like between EK and ATT the Pearson Correlation of EK is 1 and ATT is .50. So we can say that these two variables are positively correlated. Moreover correlation is significant at the 0.01 level.

4. Conclusions

This study initially examined on the second-hand textile post-purchase behaviour. Later it focused on the aspects that influence consumers' post-purchase intentions and behavior when it comes to fashion textile products. Initially the study focused on the reliability, correlation, and frequency analysis to understand the significance of each variable. The study found out that the factors: environmental knowledge, attitude, subjective norms, perceived behavioural control all positively influence on the consumer's post-purchase

intentions. But consumers post-purchase behaviour depends on many other factors. For examples consumers are knowledgeable about environmental knowledge but when it come to the after-purchase stage they do not focus more on the aspects of post-purchase behaviour. The result of this study found out that the post-purchase behaviour is not significant like post-purchase intention. Consumers have positive attitude towards purchase behaviour and post-purchase intentions but have less positive attitude towards post-purchase behaviour. According to the findings, marketers should be aware that consumers have various post-purchase behaviours while purchasing fashion textile products in the future. As a result, they should concentrate on the other aspects of it.

The study is still ongoing because of time limitations. So we aim to continue this research to know the post-purchase behaviour of the consumers and test the developed hypotheses that will enable the future scholars to better understand of the aspects like repair, reuse, recycling, and repurchasing of fashion textile consumers that may influence on their positive post-purchase behaviour.

Going Back to the Roots: Finding the positives in the old practices

Abstract

Over the last few generations, our society as a whole, has been gradually led into adopting the instant gratification lifestyle. The global apparel market is projected to grow in value to about 2.25 trillion dollars by 2025, this shows that the demand for apparel is on a steep rise across the world. Throw away fashion has been the key to promote and feed into the fast fashion cycle, wherein, consumers are splurging more than ever on apparel, wearing them less and simply discarding perfectly usable products within a season or two. This entire process in turn, is leading to uncontrollable apparel waste and ever increasing, unmanageable landfills across the world. On an average, consumers throw away almost 60 per cent on their apparel purchase within the first year, if this trend continues at the same pace, over 150 million tonnes of clothing waste will end up clogging landfills by 2050. Thanks to the media spotlight and increasing awareness people are waking up to the unsustainable aspect of fast fashion and sustainability is fast becoming a focus point. This movement counters the use and discard lifestyle by fostering a change in fashion products and the fashion system as a whole towards not just greater ecological integrity but also social consciousness. Sustainable fashion addresses the entire manner in which clothing is produced, who produces it, and how long the life span of a product is before it reaches the landfill. Thus, countering the large carbon footprint that the fashion industry in its mad dash towards higher and higher sales is creating.

This paper briefly focuses on the current sustainability practices followed by some of the fast-fashion apparel brands, if they are just seen as a rich man's game/ green-washing. The paper then investigates and analyzes if these practices are as sustainable as the traditional practices followed across the traditional Indian societies and what actually make them more applicable at grass- root levels. For this paper, various people within the traditional Indian society over the age of 40 years were questioned in order to document some of the integrated sustainable practices from their own early childhood. Wherein, the adults in the Indian traditional family/ society as a whole used to incorporate the concept of reduction, recycling and reuse into every aspect of daily life and to see if these lifestyle choices still hold true today and to what extent. We explore the current impact of these practices by using 18-30 year olds as the second focus group and analyzing their reaction to/ use of some of these practises. The results thus collected, conclusively demonstrate that the use of these traditional practices are still prevalent in our societies and they do reduce impulsive, unsustainable buying behaviour and prove the hypothesis, with some small refinements the

possibility of reintegrating these the traditional practices into daily life will continue to make an impact on a larger scale by reducing the demand for these products.

Keywords: Traditional Sustainable Fashion Practices, prevention, reduction, recycling, reuse, Fast Fashion, Impulse Buying, #ReFashionNow

1. Introduction

The production and consumption of textile products continue to grow exponentially and so does their impact not just on the climate, but on water and energy consumption as well as our environment. As per Ellen MacArthur Foundation (EMF) report, cited in the communication from the Commission to the European Parliament (2022), the global textiles production almost doubled between 2000 and 2015, and the consumption of clothing and footwear is expected to increase by 63% by 2030, from 62 million tonnes now to 102 million tonnes in 2030, as per the European Environment Agency (EEA) (2019), cited in the same communication.

At its core, the entire premise of the fashion industry is based on demand and supply just like any other business. This was in healthy balance in the past, wherein, consumers used to have to wait to get their needs catered to before moving on to their wants. With the increase in disposable incomes, (Disposable Personal Income in India increased to 238573760 INR Million in 2021 from 199689740 INR Million in 2020. Source: Ministry of Statistics and Programme Implementation (MOSPI)) and the disruptive innovations in the apparel sector; this careful balance has been upturned drastically by the fast fashion brands looking for higher and higher sales by encouraging impulse purchasing with the emphasis purely on instant gratification. Instant gratification is the desire to experience pleasure or fulfilment without delay or deferment. Basically, it's when you want it; and you want it now, Neil Patel (2014). The fast-fashion business strategy is focused on minimizing the buying cycle and lead times processes for the latest fashion trends by frequently updating their products. This system combines short manufacturing cycles, rapid distribution, and offers highly current fashion trends. Due to this production model, fashion products can reach the market almost instantaneously, this allows the fast-fashion retailers the chance to meet the consumers' wants and expectations more effectively. Some global fast-fashion companies such as Zara and H&M started using this strategy and launch new products into their stores every three to five weeks, leading to an even shorter product life cycle and thus making the fast-fashion industry one of the main drivers in environmental impact, Lidia Alexa, et al (2022).

This consumer inclination of using garments for ever shorter periods before throwing them away contribute the most to unsustainable patterns of overproduction and overconsumption. Such trends entice consumers to keep on buying clothing of inferior quality and lower price, produced rapidly in response to

keep up with the latest fashion trends. This growing demand for cheap textiles is fuelling the inefficient use of non-renewable resources, including the production of synthetic fibres from fossil-fuels. These negative impacts have their roots in a linear model that is characterised by low rates of use, reuse, repair and fibre-to-fibre recycling of textiles, and that often does not put quality, durability and recyclability as priorities for the design and manufacturing of apparel. KÖHLER Andreas et al (2021).

In the last few years, the emphasis on sustainability is being embedded across all industries and sectors due to the increasing awareness levels across the world. Studies show that consumers are more inclined to "choose a brand over another if they believe the brand will help the environment". They are also more inclined to act positively towards companies that are perceived to be sensitive to environmental concerns. In this context, starting with the late 1980s and early 1990s, Green marketing, which refers to the inclusion of environmental awareness in marketing management, has begun to be used more and more often, Lidia Alexa et al (2022). The American Marketing Association (AMA) defined green marketing as "the study of marketing activities' positive and negative aspects on pollution, energy depletion and non-energy resource depletion".

The change in consumer behaviour because of their increased awareness regarding the social and environmental impact of their fashion consumption has ensued an intensified need for more ethical alternatives, thus, generating a market demand for more sustainable products. As a result, sustainable fashion has turned into the primary focus for long-term growth and the fast fashion companies want to be associated with that image to improve their brand perception among their consumers.
